AVANT-PROPOS

Suite à une étude sur le potentiel minéral des Basses Terres du Saint-Laurent (Globensky & Ziserman, 1979), le service de Géochimie-Géophysique a procédé à un inventaire géochimique de la région de Montréal. La technique des eaux souterraines fut choisie puisqu'il s'agissait d'obtenir des informations sur un socle caché par un épais recouvrement de sédiments glaciaires et marins et qu'elle s'avérait appropriée à cause de l'abondance des puits, de son coût relativement peu élevé et du fait qu'elle permet de diminuer les problèmes reliés à la contamination de la surface de cette région. Les levés furent effectués entre 1978 et 1982 (figure 1) selon la méthodologie décrite par Lalonde & Chouinard (1983).

La région échantillonnée couvre un territoire de 8300 kilomètres carrés. Environ 200 échantillons furent prélevés dans le cadre d'un essai dans le secteur d'Oka, en 1978, et 9154 autres le furent dans le cadre de campagnes d'échantillonnage effectuées entre 1980 et 1982. La densité moyenne d'échantillonnage qui est de 1.1 éch./km^2 est donc excellente pour définir des cibles d'exploration de nature locale.

Vu que les travaux furent effectués sur une période de trois ans, qu'il y a des différences au niveau des paramètres dosés et des méthodes analytiques utilisées et que l'échantillonnage touche à deux régions géologiques très différentes (Grenville et Basses Terres), nous avons regroupé les données en deux parties de huit sections chacune (1A à 1H et 2A à 2H).

Les sections 1A, 2A, 1B et 2B contiennent les données analytiques pour les différents dosages: métaux traces (Cu, Zn, Pb, Ni, Co, As, Hg, U, Ba, Fe et Mn), éléments alcalins (Na, K et Li), terres alcalines (Ca et Mg), halogènes (F et Cl) et quelques autres paramètres (SO_4 et C). Les méthodes d'analyse sont décrites dans Guimont & Pichette (1980).

Les sections 1C et 2C contiennent les observations codifiées lors du prélèvement des échantillons: profondeur des puits, type de puits, nature du fond géologique, etc. Les informations non codifiables décrivant le revêtement des puits, les sources de contamination et autres particularités, sont regroupées aux sections 1D et 2D, intitulées "informations additionnelles".

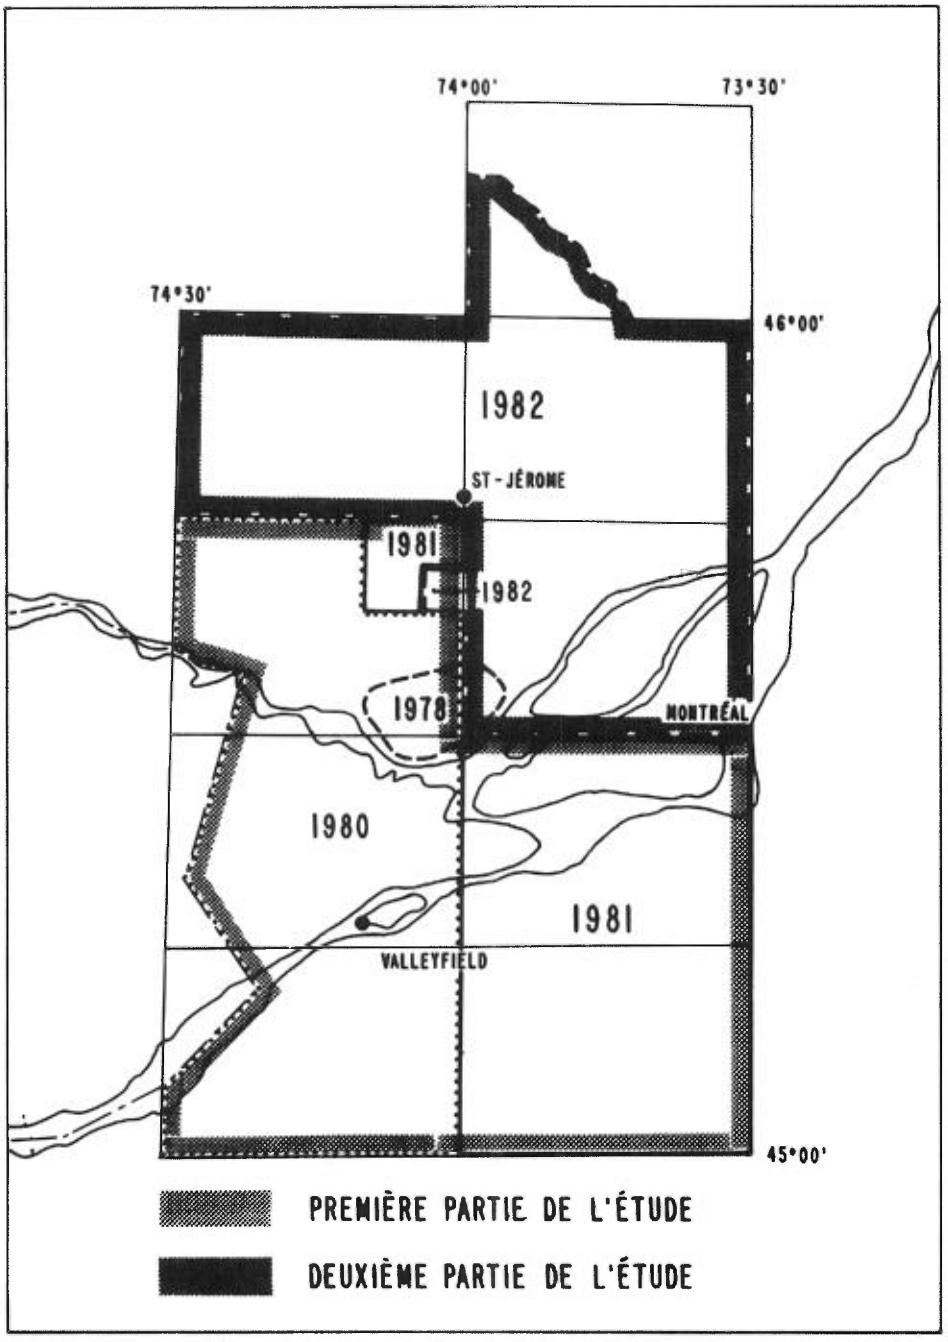

FIGURE 1 - Localisation des levés d'échantillonnage dans la région de Montréal.

Les sections 1E et 2E (annuaire des sites d'échantillonnage) complémentent les cartes de localisation (sections 1G et 2G). Elles fournissent l'adresse postale et le nom des propriétaires ou locataires où sont situés les puits échantillonnés.

A noter que, dans la partie 2, les statistiques concernant les échantillons prélevés en terrain grenvillien sont présentées séparément de celles des Basses Terres. Dans ces deux milieux, les niveaux de teneur pour la plupart des éléments sont nettement différents.

Les sections 1F et 2F regroupent des tests de normalité et de log-normalité, qui permettent au lecteur d'avoir une première vision statistique des données analytiques. On y retrouve les histogrammes de distribution, les moyennes, les écarts-types, etc. Les tests ont servi à choisir les classes pour la représentation cartographique des données à inclure dans l'atlas géochimique sur la région de Montréal (Pelletier & Lalonde, en préparation).

Les sections 1G et 2G correspondent aux cartes de localisation des sites d'échantillonnage (secteurs sud et nord). Ces cartes, à une échelle de 1:100 000, comprennent les coupures topographiques SNRC suivantes: 31 G/01, 31 G/08, 31 G/09, 31 G/16, 31 H/04, 31 H/05, 31 H/12, 31 H/13 et 31 I/04.

Les sections 1H et 2H, présentées en cinq feuillets (hors texte), comprennent les cartes de compilation des données. Ces cartes, intitulées COMPILATION RÉGIONALE, COMPILATION LOCALE et COMPILATION INTERMÉDIAIRE, délimitent de nombreuses aires d'activité géochimique qui devraient permettre aux explorationistes d'orienter leurs travaux d'exploration. Les polygones multiples que l'on trouve sur ces cartes ne regroupent que des sites à teneurs élevées en plusieurs éléments; ils ne définissent cependant pas la totalité des aires d'intérêt. **A noter ici que la carte de compilation intermédiaire n'a pas été dressée pour la partie nord de la région.**

La compilation régionale présente de grandes aires d'activité géochimique telles que les complexes géochimiques ou les ceintures géochimiques (Lalonde, 1983) reliées à des lithologies, métallotectes ou phénomènes géochimiques régionaux. Les compilations **locale** et **intermédiaire** mettent en évidence des aires d'activité restreintes qui sont habituellement à proximité des sources des signaux. Chacune des aires d'activité géochimique sur les compilations locale et intermédiaire ont

reçu une cote de priorité définie en fonction de critères objectifs et/ou empiriques. Cette cote fournit à l'explorationiste un critère additionnel pour juger de la valeur des signaux géochimiques observés.

Les critères utilisés pour réduire l'information et en évaluer les priorités sont décrits sur chacune des cartes de compilation. Plusieurs autres cartes de réduction d'information pourraient être faites en prenant des critères différents. La tâche d'évaluer la pertinence des signaux observés ou de réajuster la réduction d'information en fonction de certains environnements particuliers est laissée à l'utilisateur.
