Notes: Lac Winchester Project. Dec. 1984 (to be included final assessment rep't)

Geology:

The three claim groups totalling 323 claims were prospected and partly mapped during Sept & Oct, 1984. Outcrop is scarce. Practically all samples collected during prospecting and mapping were assayed for gold, and while anomalous values were noted, none were of economic grade. Most of the work was concentrated on the largest claim block, the Lac Winchester Group. Of the two smaller blocks to the south, the Gamache Group (14c1) was found to be completely overburden covered, while the Opawica Group (12c1), while having some outcrop, was found to be apparently barren of the mineralized float which was reported to have occurred there.

Most attention was concentrated on the eastern part of the Lac Winchester Group, where a number of mineralized outcrops were seen and subsequently trenched and mapped. In this area a N dipping sequence of blocky tuffs of variable composition is flanked on the south side by a thin chert/oxide IF which in turn is flanked to the south by a series of gabbroic and pyroxenitic rocks exhibiting in some cases extreme degrees of carbonate alteration. A major structural discontinuity separates the IF and the blocky tuffs; this is possibly an unconformity, in which case the section is overturned and south facing - similar to the situation at Chibex, some 13 miles to the east. Structures in this area are moderately east plunging. Alteration is extensive in both the tuffaceous rocks and the gabbro/pyroxenite sequence, and is characterized by extensive carbonatization and widespread development of chloritoid. The former is particularly marked in the Gravel Pit area, while the latter is characteristic of the Esso and Road Trench areas some 4000' to the west along the same structure. These types of alteration are typical of areas hosting gold mineralization and although work to date has only realized trace values, the extent and degree of alteration is such that a halo effect is present and further examination is essential.

Geochemistry:

Recon basal humus geochem' was carried out along 100m spacings on the roads. Values of up to 55ppb Au were outlined, and although the significance of these anomalies can be debated, they are, in a regional context, highly anomalous. The method, because of its speed and cheapness should be expanded on, and followed up by extensive basal till sampling

Geophysics:

The gradient mag is very useful in outlining major formational trends. For example, the IF sequence shows up as a well developed positive gradient anomaly, which can be traced some 4½ miles across the Lac Winchester Group. Interestingly, a number of gaps occur in this anomaly along its length. This may be due to local absence of the IF, but it might also reflect destruction of magnetite through pyritization - a phenomenon which was observed on a small scale in the eastern structures above. Again, this type of mineralization is typical of certain types of gold deposits.

An Input survey also covers the area, and a systematic effort should be made to reinterpret and relocate these anomalies on the present air photo mosaic basemap.

Golden Tiger has carried out VLF surveys on 4 grids spread out over the Lac Winchester Group, confirming the presence of many of the Input and airborne VLF anomalies.

Conclusions:

1) Further attention should be paid to the eastern sector of the property; the extensive alteration together with the presence of basic to acid fragmental rocks suggesting volcanic centre proximity indicates a favourable environment for gold and base metal mineralization.

Ministère de l'Énergie et des Ressources

Service de la Géoinformation

Date: 7 MARS 1986

No G.M.: 42628

Notes: Lac Winchester (2 Of 2)

Conclusions, cont'd.

2) An inventory should be made of all conductors on the property, both Input, airborne and ground VLF, and some attempt should be made to link them with the various formational boundaries outlined by the airborne gradient.

3) Screening of this inventory should be made through both humus and basal till geochemistry. The results from the humus sampling indicate that considerable and apparently systematic variations exist in humus gold contents over the property.

Footage from-to	Description
0- 10	Casing
10-92.9	Tuff, med gry, vfgr, homogeneous, carbonatized, med hard, occ lapilli and small med gry angular frag visible. Bd not well def., but tends to be about 80° c.a. Occ. 1/8 - 1/4" wh qtz stringers & veins // bd.; streaks of py, po locally // bd. Sulph overall v. low, less 1/2%. Hairline fractures // to 10° c.a. & exhibiting narrow bleached selvages here & there. Colour of rock tends to darken & become more greenish from 60' on down. 60-61.1' wh qtz veins @ 80° c.a. form a banded zone that resembles the cherty IF seen at surface in the Gravel Pit some 700 metres west. From 88' to 92.9' the section is characterized by heavy py/po in the bedding (80° c.a.) Py po in about equal proportions; traces of sphalerite seen. Lower contact of unit sharp, 80° c.a. In general the sulphide zones seem to be margined by a chloritic halo - the 'darkening' described above. Loc. fine diss magnetite.
