REPORT ON HEAVY MINERAL EXAMINATION AND ANALYSIS DIAMOND DISCOVERIES INTERNATIONAL TORNGAT DIAMOND PROJECT, QUEBEC

I. INTRODUCTION SUMMARY

This report summarizes visual examinations of heavy mineral concentrates and electron microprobe analyses of mineral grains selected from the heavy mineral concentrates. The heavy mineral concentrates consist of: 1.) detrital material derived from till and stream gravel samples; 2.) crushed rock samples; 3.) residues from partial caustic (acid) digestions of rock samples. The heavy mineral concentrates were collected by Diamond Discoveries International during the 2001 field season on the Torngat Diamond Project situated in the Torngat area of the Ungava region of northern Quebec.

The program resulted in the identification of minerals commonly associated with kimberlite and unique rock types akin to kimberlite. Kimberlite minerals identified by the program include: pyrope garnet, chrome diopside, olivine, phlogopite, perovskite, Mg ilmenite, chromite, enstatite, Cr amphibole, potential eclogite almandine garnet, corundum and clinopyroxene. The program also identified minerals associated with base metal deposits and sulphide zones.

LOGISTICS

Between August and November, 2001 Diamond Discoveries International sent heavy mineral concentrates for petrologic examination to Robert Dillman(author) of Arjadee Prospecting located in Mount Brydges, Ontario. The heavy mineral concentrates consist of mineral grains derived from till and stream gravels, crushed rock and partially digested rock residues from caustic (acid) fusion diamond analyses.

A total of 217 heavy mineral concentrates were sent to Arjadee Prospecting. The concentrates consisted of 191 till and stream gravel samples, 7 crushed rock concentrates and 19 caustic fusion residues.

Heavy mineral concentrates were examined by the author between September 2001 and June 2002. The concentrates were examined under 7x to 50x magnification using a binocular microscope. A description of each concentrate examined is appended to this report. The descriptions are based on specific grain counts and modal percentages derived on visual approximations.

Individual mineral grains selected from specific samples were identified by an electron microprobe. The microprobe is owned and operated by Robert L. Barnett of R.L. Barnett Geological Services located in Lambeth, Ontario. Mineral chemistries obtained by microprobe analyses are appended to this report.

SAMPLE PREPARATION

Heavy mineral concentrates derived from till and stream gravels were concentrated by personnel of Diamond Discoveries International. The concentrates were screened and prepared at an on-site facility. Samples were separated into coarse-, medium- and fine-grained fractions by sieving with 2.0 mm, 1.0 mm and 0.5 mm screens. Minerals were concentrated by specific gravity using a mechanical jig.

Mineral residues derived from acid digestion of potential diamond-bearing rocks found on the Tomgat property were prepared by Lakefield Research at facilities in Lakefield, Ontario. Lakefield Research produced mineral concentrates by screening and mineral separation based on magnetic susceptibility of individual grains.

Heavy mineral concentrates made from rock samples received by Arjadee Prospecting were crushed using an impact crusher, screened and concentrated by mechanical jig. Concentrates derived from jig were concentrated to a minimum specific gravity of 3.0 g/cm³ using the density separation liquid: lithium metatungstate.

Magnetic minerals were removed from many of the concentrates using a magnetic tray. Magnetic fractions have been stored for future reference. Finally, each component of the heavy mineral concentrates was weighed and information recorded on the concentrate description sheets accompanying this report. Currently, mineral concentrates are stored at facilities provided by Arjadee Prospecting.

RESULTS

Kimberlite indicator minerals and minerals associated with rock types akin to kimberlite have been identified in heavy mineral concentrates from the project. Table 1. summarizes the electron microprobe analyses of the kimberlite minerals. Table 2. is a compilation of results based on mineral verification by the electron microprobe combined with the results of visual examination of the concentrates and grain counts.

KIMBERLITE AND ASSOCIATED MINERALS

Three mineral suites represent kimberlitic and lamprophyric rock units on the property. The mineral suites and a representative samples-type where the minerals are dominant include:

- 1.) DRX-3: kimberlite indicator mineral suite including: pyrope garnet, chrome diopside, chromite, picroilmenite, phlogopite, magnetite, olivine, enstatite and eclogite garnet.
- 2.) 5262: andradite garnet, perovskite, magnetite, phlogopite, chrome diopside and olivine.
- 3.) DDI-3-30: chrome diopside, enstatite, phlogopite, olivine, apatite, pyrite, ilmenite and eclogite garnet.

Photographs of the three mineral suites accompany this report. Plots of the minerals chemistries and comparisons to known diamond-bearing kimberlite are presented in Figure's 1 to 4.

Pyrope Garnet

All but one pyrope garnet occur in the DRX series of concentrates. Two of the samples are caustic digestion residues of rock samples collected on the property. Pyrope garnet is most prolific in the detrital sample: DRX-3, totaling approximately 25% of the heavy mineral concentrate.

The composition of selected pyrope garnets from the DRX- series of concentrates determined by electron microprobe analysis are similar to garnet occurring in typical kimberlite. The compositions correspond to "G9" type pyrope.

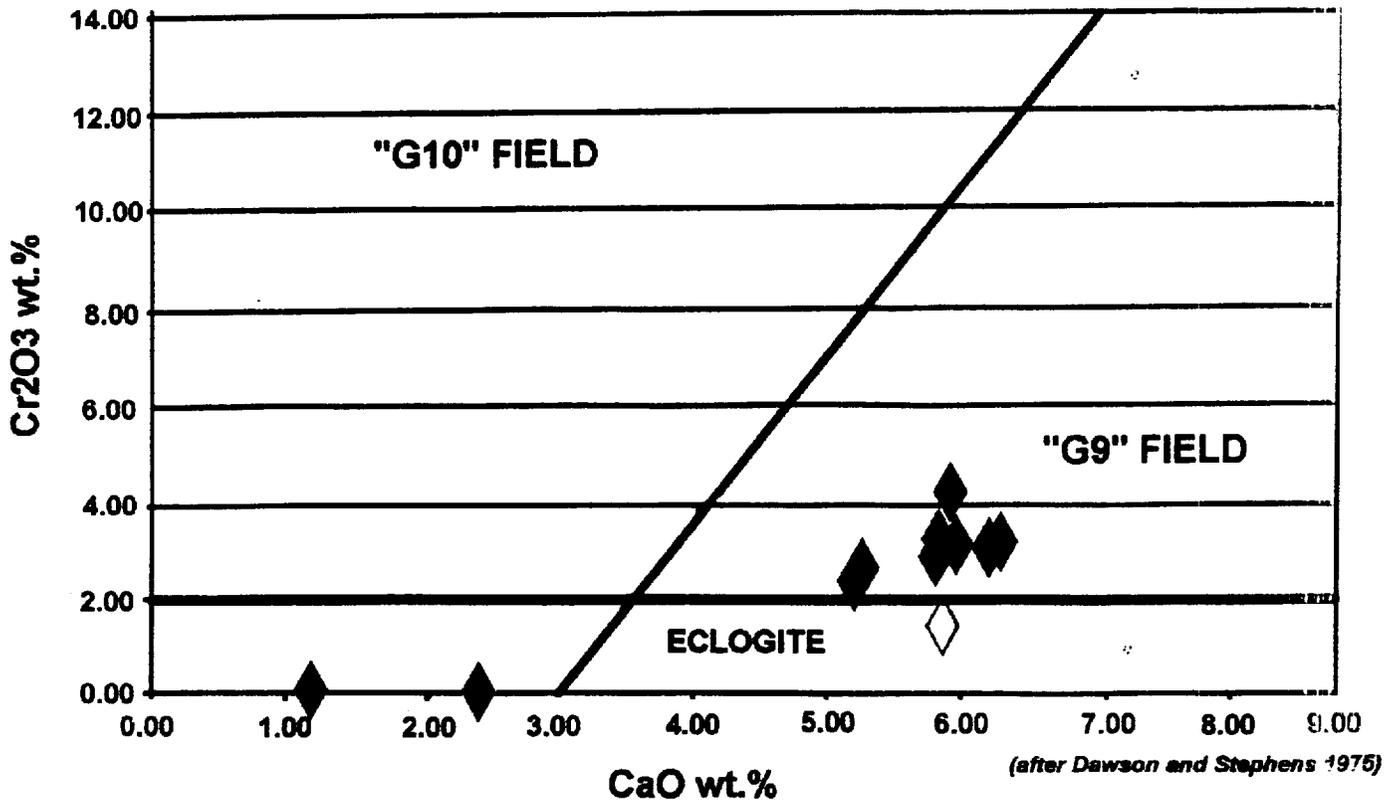

A single grain of pyrope was found in sample XP-8. The chemistry of the grain shows a slight increase in CaO suggesting a potential eclogite association. Chrome diopside was also found in the sample.

Chrome Diopside

1 to 6 grains of typical kimberlitic chrome diopside occur as detrital grains in seven of the DDI-3 series of samples. It is reported by Diamond Discoveries International that the samples were collected in the vicinity to several newly discovered pipe-like bodies of potential kimberlite.

Chrome diopside is most abundant in sample DRX-3 where it totals approximately 5% of the concentrate. Some of the chrome diopside in the sample occurs as intergrowths with pyrope garnet. Intergrowths of mantle fragments

SAMPLE DRX-3 & XP-8
TORNGAT PROJECT, QUEBEC
DIAMOND DISCOVERIES INTERNATIONAL

attest to the complex environment of upper mantle regions and could represent favorable conditions for diamond growth.

Chrome diopside has been observed in several hand samples of kimberlitic material. Chrome diopside occurs as inclusions in 3 to 5 cm sized mantle nodules of olivine. In the concentrate of crushed rock sample DDI-3 SOUTH PIPE, chrome diopside totals approximately 5% of the mass of the nodule. Small inclusions of chrome diopside also occur in pellet-shaped olivine nodules found in several concentrates containing perovskite.

Microprobe analyses of the various chrome diopside grains found during the program coincide directly with typical kimberlite compositions of both diamond and non diamondiferous kimberlite. Some chrome diopside appear to be chemically zoned as evident by an increase of Na₂O on the margin of some grains. Increasing Na is usually associated with eclogitic clinopyroxene. Clinopyroxene with <1.0% Cr₂O₃ have typical augite compositions and may also have an association with eclogite terrains as Na increases.

Perovskite

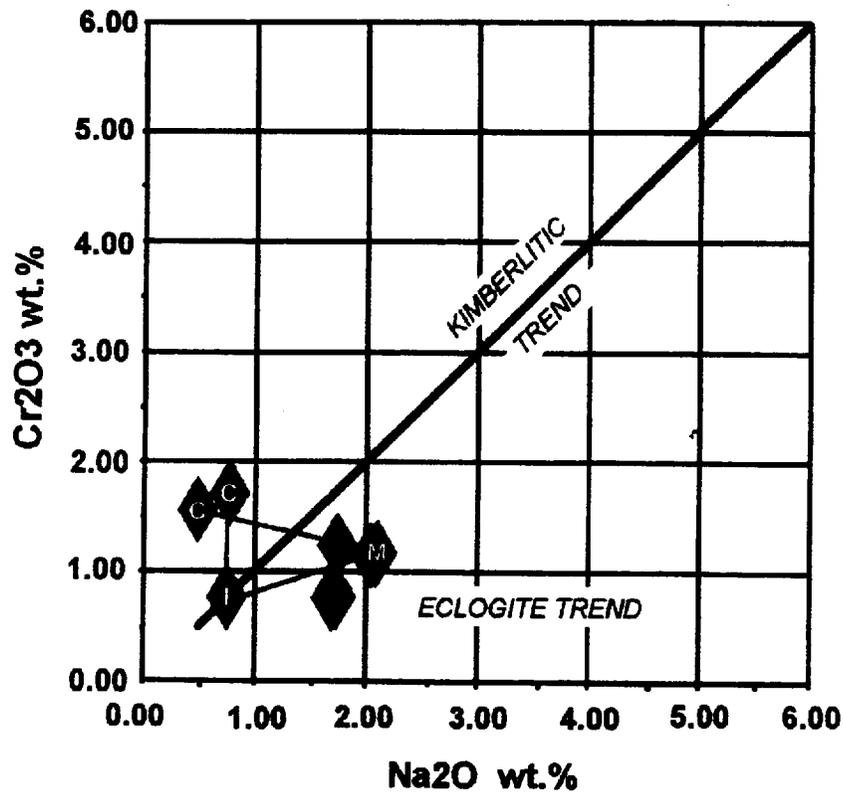

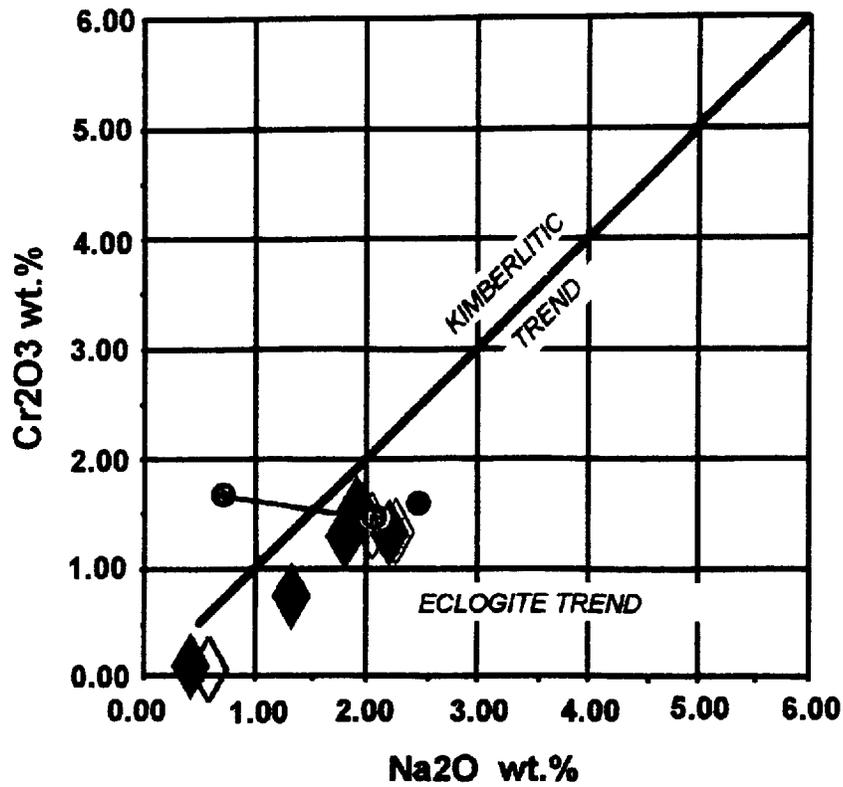

It is apparent by the presence of perovskite that different types of heavy mineral suites are associated with the various dikes found throughout the area. Perovskite is most prolific in the ARX / ARY series of concentrates where it totals 5 to 80% of the concentrates. Perovskite occurs in a crushed rock sample concentrate made from sample 5291. Perovskite also occurs with chrome diopside in DDI-3-16 and DDI-3-35.

Although complete microprobe analyses have not been completed, perovskite has been identified by R.L. Barnett using the E.D.S. system. Perovskite is a common mineral in kimberlite and is usually associated with groundmass material where it occurs as small crystalline grains. Perovskite found in concentrates collected in the project area occur as very small euhedral octahedral-shaped crystals in direct association (sometimes as inclusions) with large coarse grains of clear and yellow olivine and coarse- megacrystic phlogopite.

Olivine

Table 2. shows olivine is a major component of concentrates containing kimberlite and related indicator minerals. In concentrates, olivine occurs as fragments and pellet-shaped grains and in several hand samples, is seen as lens-shaped masses up to 5 x 3 cm in size. It is believed the pellets and large masses represent nodules of mantle material transported to surface via the rock enclosing the nodules. Some nodules of olivine contain inclusions of kimberlite minerals.

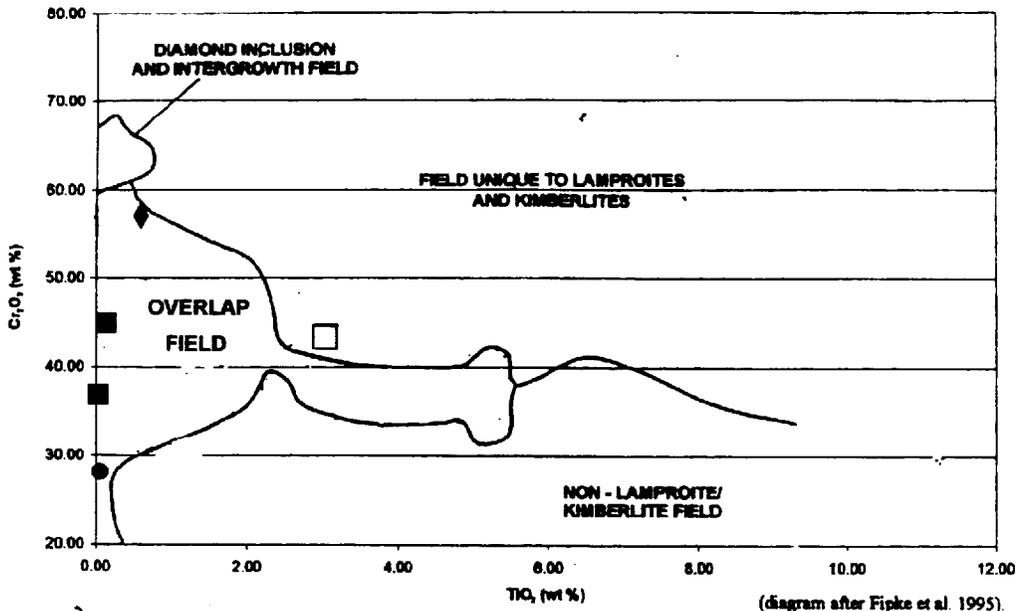

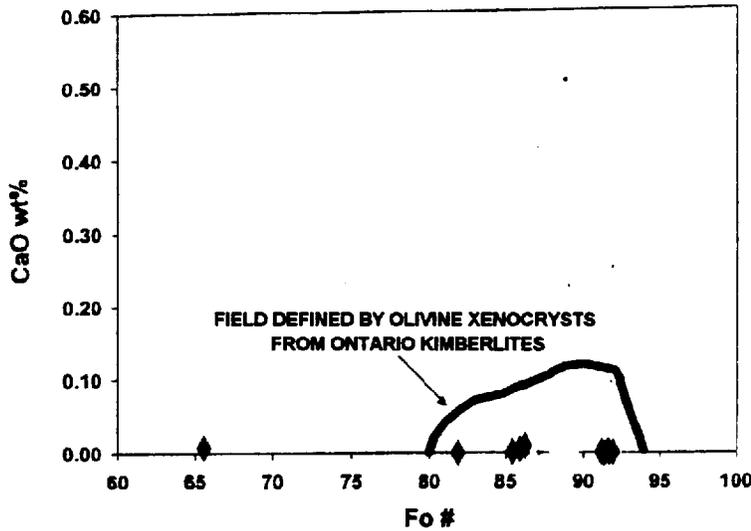

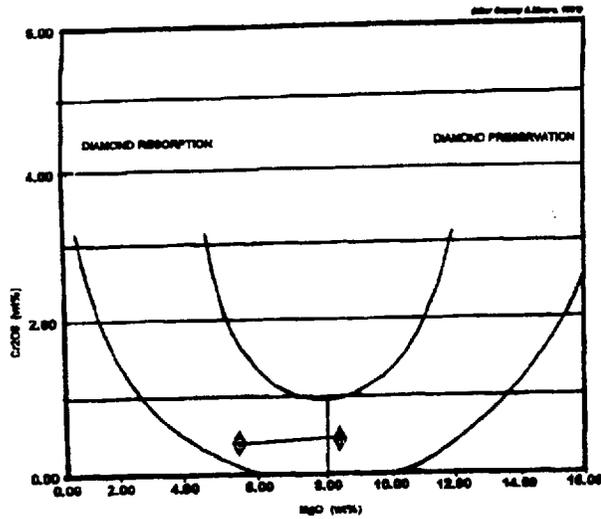

FIGURE 4.
CHROMITE, Mg-ILMENITE & OLIVINE PLOTS
TORNGAT PROJECT, QUEBEC
DIAMOND DISCOVERIES INTERNATIONAL

Olivine associated with the dikes and heavy mineral concentrates collected in the project area are comparable to typical olivine found in both diamond and non diamondiferous kimberlite. Microprobe analyses of a number of grains show the majority of olivine is fosteritic with weighted modal percentages of MgO ranging in excess of 90% (Fo91-93). The presence of olivine in any heavy mineral concentrate indicates a source close to the sample site since olivine has a lack of resistance to weathering and is very susceptible to destruction by erosion.

Kimberlite minerals occurring as inclusions in the olivine nodules may have been incorporated before crystallization of the olivine. This would limit the distribution of kimberlite minerals (and potentially diamond) throughout the transport rock. In sample DRX-3, large grains of olivine occur separately with the kimberlite minerals, thus appearing to have crystallized simultaneously. This would not restrict the number and distribution of mantle fragments (pyrope, chrome diopside, olivine, diamond) throughout the transport rock.

Phlogopite-biotite Mica

Phlogopite-biotite mica is a major component of rock samples and heavy mineral concentrates collected in the vicinity to the kimberlite/ lamprophyre dikes occurring in the project area. Characteristically, the mica occurs as large flakes ranging 0.1 to 1.0 cm in diameter and are easily seen in the concentrates without the aid of a microscope. Colour varies with iron content and zoning is evident in some grains (Photograph 4). Biotite is generally dark brown or green and phlogopite tends to be black, silver or light brown.

In most rock samples, fine-grained mica is a major component of groundmass material. Interstitial mica occurs with olivine, serpentine, calcite, clinopyroxene, perovskite and magnetite. Biotite rich groundmass tends to be associated with lamprophyre. Due to abundance and ease of mobility, mica is usually the first recognizable detrital mineral to indicate the presence of kimberlitic/ lamprophyric rocks in the vicinity to a sample site.

Andradite Garnet

Andradite garnets (melanite) are associated with perovskite-mica-olivine bearing dikes and heavy mineral concentrates. The garnets are typically dark brown or black in colour and occur as euhedral crystals up to 1 cm in diameter.

Chromite

Five chromite grains were verified by microprobe analysis. The Cr₂O₃:TiO₂ ratios of 4 grains are non definitive with respect to source although 2 of the chromite grains were found with kimberlite minerals in sample DRX-3. A single grain of Ti-chromite was found in sample Chassin-1 (CH-1). The composition of this grain coincides with chromite unique to kimberlite and

lamproite. The highest Cr ratio, 56.25% wt. Cr₂O₃, was detected in H2RX-10 (H2-10). This sample contains large volumes of phlogopite and other kimberlite minerals. A single grain of chromite occurs with chrome diopside in sample DDI-3-30 (3-30). It is reported by Diamond Discoveries International, the sample was collected in the vicinity to several recently discovered pipe-like structures.

Mg Ilmenite

A total of 19 Mg ilmenite grains were verified by the electron microprobe. Only one grain contains sufficient Cr₂O₃ to be considered picroilmenite. Sixteen ilmenite grains were recovered from rock sample 5294. The composition of the ilmenite plot as three distinct fields possibly reflecting: 1.) analyses on various fragments of zoned ilmenite grains; 2.) potential crystallization of ilmenite at different periods during magma ascent; 3.) introduced by crustal fragment collected as xenoliths during ascent.

A single grain of picroilmenite was detected in the concentrate of H2RX-10 (H2-10). On the basis of MgO, the microprobe analyses indicates the ilmenite is zoned. Composition as indicated by the grain margin suggests, if diamond is present conditions were favorable for diamond preservation as magma ascended. The core of the grain has similar chemistry to ilmenite in rock sample 5294.

Enstatite

9 grains of enstatite were identified by the microprobe. In sample DRX-3, enstatite is light-brown in colour and grain surfaces have weak schiller reaction with light. 4 grains of a dark green variety have been identified in rock sample 5294. Dark green enstatite also occurs in most of the DDI-3 series of samples containing chrome diopside. Enstatite is widely dispersed and is considered a good indicator for locating potential kimberlite and lamprophyre within the project area. Heavy mineral concentrate DDI-5-14 appears to contain as much as 3% enstatite although the grains have not been verified by microprobe analyses.

Ca-mg Almandine Garnet

90% of the garnet analyzed by the microprobe are calcium and magnesium bearing almandine garnet. The composition of the garnets overlaps with the eclogite garnet field found in kimberlite and with non kimberlite compositions such as those found in eclogite terrains within certain metamorphic environments. In the area of the survey, similar compositions and colours of garnet to those analyzed occur in abundance in rock units underlying the project area. For this reason, Ca-Mg almandine garnets are difficult to use as an indicator mineral of kimberlite and related rocks in this region.

Most of the Ca-Mg almandine analyzed by the microprobe were selected from samples containing kimberlite and related indicator minerals. The garnets could represent eclogite carried by the source of the kimberlite minerals. In sample DRX-3, which appears to consist of 100% kimberlite minerals, approximately 30% of the concentrate are orange Ca-Mg almandine garnet. The composition of the orange almandine do not have any certain features such increasing Na to distinguish the garnets from region sources. In DRX-1 and DRX-2 digestion residues, pink and orange Ca-Mg almandine occur with pink corundum and lesser quantities of graphite. Pink corundum and graphite occur in eclogite in diamond and non diamond bearing African kimberlite. Potentially, graphite may have been derived from xenoliths of country rock which in some areas are graphite-bearing.

Distinctive orange Ca-Mg almandine occur in several of the kimberlite mineral bearing samples of the DDI-3 series.

Pink Corundum

Lakefield Research identified pink corundum in residues of the DRX digestion samples. 303 grains of corundum were counted in the DRX-1 residue. Corundum forms approximately 80% of total residue of DRX-4. Corundum grains from sample DRX-2 were verified by microprobe.

Corundum eclogite is known to occur in diamond and non diamond bearing kimberlite. It is commonly associated with graphite in eclogite. Graphite flakes also occur in the residues of DRX series rock samples. Both corundum and potentially graphite represent some eclogite component within dikes tested.

Visually, pink corundum resembles pink almandine garnet and the author had difficulty separating the two minerals apart. Mineral counts and modal percentages for corundum should be regarded with caution until adequate microprobe analyses supports the various amounts of potential corundum seen throughout the samples.

Sphene

Orange sphene was a common constituent in the heavy mineral concentrates derived from detrital material. Orange sphene was frequently observed with large amounts of almandine garnet and probably has some regional metamorphic association.

A particular variety of yellow sphene occurs with chrome diopside in several DDI-3 series samples and in rock samples: 5294, H Dike and K Dike. The

relationship of sphene with the various dikes and pipes in the project area is uncertain. It is believed the sphene has an eclogite association similar to corundum. Some sphene observed in concentrate are in excess of 1.0 mm, clear yellow and inclusion-free and of potential gem quality.

Cr Clinopyroxene and Na Augite

Chrome clinopyroxene have <1% weight Cr₂O₃ oxide and sufficient FeO to be considered an augite. An increase in Na increases the potential to be eclogitic. Composition of some augite found within the survey area weakly overlap kimberlitic trends displayed by clinopyroxene and should be regarded with caution as to speculation of origin. Similar compositions of clinopyroxene can occur in a wide variety of non kimberlitic rocks. Future exploration should emphasis on areas where clinopyroxene occurs in concentrates with kimberlite minerals. Potential eclogitic clinopyroxene occur with kimberlitic minerals in DDI-3 series samples. Potential eclogitic Na augite occurs with pyrope, chrome diopside and Ca-Mg almandine garnet in sample XP-8.

Chrome Amphibole

Seven grains of Cr amphibole were confirmed by microprobe analyses in 3 samples. The amphibole occurs with Na augite in all three sample and with Ca-Mg almandine garnet in only two of the samples. The amphibole could be the product to alteration of a chrome bearing augite or diopside. Three Cr amphiboles where found in each of the heavy mineral concentrates: VEN-2A and MCW-3.

Magnetite

Magnetite is a major component of the lamprophyre/ kimberlitic rocks found on the property. In these rocks, magnetite occurs as fine groundmass material and as small inclusions in mica. During processing, magnetite was not removed from most concentrates of kimberlitic/lamprophyre material. In DRX-3, Ti-magnetite occur as megacryst pellet-shaped grains with an orange, rust-like rind coated the grain surfaces.

In the project area, the magnetite content of detrital-type heavy mineral concentrates generally increases in the vicinity to ultramafic rocks.

Massive magnetite was observed in the concentrates of sample MCSS-5 /DDI-3 and sample DDI-3-23. In DDI-3-23, 27 grains of magnetite were coated in malachite and azurite.

Rutile

Rutile is a common accessory mineral in a majority of the detrital-type heavy mineral concentrates collected in the project area. Most of the rutile found

in the project area occur with derived garnets derived from local metamorphic sources. Rutile totals approximately 5% of the concentrates in: DDI-5-3, DDI-5-17, DDI-6-33, DDI-6-34, DDI-3-58, MC-5, MC-12, MC-14 and AY-3. Approximately 10% rutile is reported in sample MC-13. These samples represent potential garnet-titanium targets.

Apatite

Apatite is present in most digestion residues, crushed rock sample concentrates and in several of the DDI-3 series of concentrates containing kimberlite minerals. Apatite is a common constituent of kimberlite and related rocks. Apatite associated with the kimberlitic/ lamprophyric rocks in the project area is clear and colourless and occasionally in euhedral crystal form.

Pyrite

Detrital grains of pyrite are common in concentrates collected in areas where amphiboles are a major component of the concentrate. Of particular interest are euhedral grains of pyrite found in the DDI-3 series of concentrates containing kimberlite minerals. The pyrite cubes in these samples are very distinctive due to a red tarnish on grain surfaces. Pyrite is commonly found in various environments in kimberlite and has no relevance to the diamond potential.

Ilmenite

Ilmenite rarely occurs in heavy mineral concentrates collected in the project area. A significant increase in ilmenite was observed in several of the kimberlite mineral bearing samples of the DDI-3 series. The ilmenite has compositions comparable to crustal ilmenite. Ilmenite may have been introduced in xenoliths carried by the pipe structures discovered in the area.

III. DISCUSSION OF RESULTS

Diamond Discoveries International has found rocks and minerals which are associated with kimberlite or ultramafic rocks closely akin to kimberlite. Definitively, to affix the ultramafic rocks found in the project area with the name 'kimberlite' could be premature since detailed microprobe, whole rock and petrographic analyses are needed to properly match the nomenclature of kimberlite. The terms: 'kimberlite' and 'lamprophyre' have been used throughout this report as a matter of simplicity since (based on compositions of heavy mineral concentrates) no other rock name(s) could be appropriate at this time.

The majority of samples containing kimberlite minerals were collected on or very close to the sources of the kimberlite minerals. The dispersion and abundance of kimberlitic and related minerals is very limited with increasing distance from source. Limited distribution could be attributed to: 1.) glacial history; 2.) recessed nature of ultramafic rocks; 3.) rugged topography; 4.) lack of till cover. When kimberlite minerals are detected in heavy mineral concentrates, the potential for the minerals to be from a local source appears to be strong.

Speculation of diamond potential based on the results of this heavy mineral survey can not be accurately made since G10 pyrope garnet and diamond-inclusion chromite (considered by some to reflect diamond potential) were not found by this survey. It should be noted that Lakefield Research did identify diamonds in several of the dikes found in the project area and diamond-inclusion chromite was identified (in sample: H1SS-100) by a previous heavy mineral survey performed by Diamond Discoveries International. Additional analyses of potential kimberlitic grains (pyrope, eclogite garnet and black metallic grains) which have been selected but not analyzed by the microprobe could result in the detection of additional diamond indicator minerals. It is also possible the majority of diamond indicator minerals will be found in the residues of caustic digestion similar to the distribution of G9 pyrope found by Lakefield Research. It is considered by author that there is good diamond potential of the rocks on the property containing fosteritic olivine (eg. DDI-3 SOUTH PIPE) since the olivine compositions are comparable most diamondiferous kimberlite containing similar olivine mantle fragments. Olivine with >90% MgO suggests crystallization within mantle conditions with sufficient pressure and temperature to promote diamond growth. The abundant eclogite minerals found in the heavy mineral concentrates associated with the dikes and pipes clearly dictates the diamond potential needs to be explored further.

IV. CONCLUSION AND RECOMMENDATIONS

Heavy mineral concentrates collected by Diamond Discoveries International in the Tomgat region contain kimberlite minerals. Many of the heavy mineral samples were collected on or very close to the source of the minerals. Concentrates made from kimberlitic rocks found in the project area also contain kimberlite minerals. Compositions of the kimberlitic minerals determined by an electron microprobe are similar to diamond and non diamond bearing kimberlite. An abundance of potential eclogite minerals were also found with the kimberlite minerals. Diamonds are frequently found in eclogite xenoliths in kimberlite.

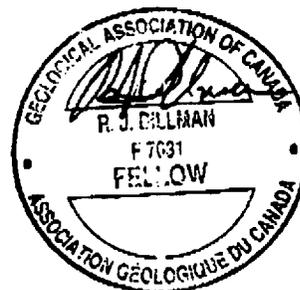

Additional heavy mineral sampling and ground exploration is recommended in the vicinity to samples containing kimberlite minerals. Emphasis should be placed on any region where olivine is present. Diamond analyses is recommended for the pipe-like structures reported to occur in the vicinity of the kimberlite-bearing DDI-3 series of concentrates. Diamond analyses is also recommended on any dike containing coarse olivine. Particular interest should be given to rocks containing perovskite, H2RX-10 and to any rocks with corundum, particularly represented by the DRX- series of samples.

Sincerely,

Robert J. Dillman B.Sc.
Arjadee Prospecting

AMPHIBOLE (IGNEOUS)

September 21, 2001

Mr. Robert Dillman,
For:
Mr. Peter Farderber,
Diamond Discoveries International,
C/O Prospecting Geophysics Ltd.,
117 Rue Villeneuve,
VAL D'OR, Quebec Fax 1-819-824-3966.

R. L. Barnett Geological Consulting,
9684 Longwoods Road,
RR32, London,
Ontario, N6P 1P2 Ph 1-519-652-1498 Fax 1-519-652-1475

Dear Bob,

For your records, the purpose of this letter is provide information concerning the nature and fate of mineral grains for which analyses were not provided in the batch of grains given to me with your letter of September 3, 2001. These grains were identified using the EDS system on the microprobe during the course of mineral analyses.

Sample DEX-3 - grains 21,23 - Ti-magnetite
Sample CH-1 - grains 2,3,7,8,9,11 - magnetite
 grains 4,6,9,10,12- ilmenite
Sample MC-2 - grain 3,4 - epidote
 grain 5,6,7,9,10 - spessartine-almandine ss.
 grains 14,15 - ilmenite
Sample AY-2 - grains 5-12 - rutile
Sample VEN-2A - grains 5-7,11-16 - ilmenite
 grain 17 - rutile
 grains 8-10 - Fe clinopyroxene
Sample 6-12 - grains 1,4,58 - rutile
 grains 2,36,7 - ilmenite
Sample 6-17 - grain 1 - rutile
 grain 2 - ilmenite
 grain 3 - rutile + ilmenite
 grain 4 - Ti-magnetite

Sincerely,

R. L. Barnett

Ph 1-519-652-1498 Fax 1-519-652-1475

Dear Bob,

For your records, the purpose of this letter is provide information concerning the nature and fate of mineral grains for which analyses were not provided in the batch of grains given to me with your letter of September 11, 2001. These grains were identified using the EDS system on the microprobe during the course of mineral analyses.

Sample MC-3 - grain 3 - amphibole

Sample MC-5 - grains 4-9 - ilmenite

Sample MC-9 - grains 1,5 - almandine
grain 2 - grossular-almandine ss.
grain 4 - lost

Sample MC-10 - grain 3 - sphene
grain 6 - amphibole
grains 7,8 - ilmenite
grains 9,11 - pyrite enclosed in Fe oxide

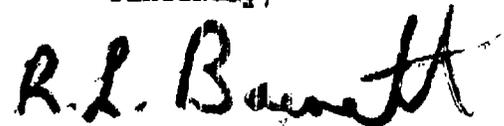

Sample MC-13 - grains 7-12 - ilmenite

Sample MCW-3 - grain 6 - Fe oxide - possible welding band

Sample MCW-6 - grain 4 - monazite
grains 10,16 - amphibole
grain 12 - apatite
grain 14 - rutile
grains 13,15,17 - Fe clinopyroxene

Sample MCW-8 - grain 4 - grossular-almandine ss.
grains 10,12,14 - ilmenite
grain 11,13 - amphibole
grain 15 - rutile

Sincerely,

A handwritten signature in black ink, reading "R. L. Barnett". The signature is written in a cursive style with a prominent, sweeping flourish at the end of the name.

R. L. Barnett

Mr. Robert Dillman,

Ph. 1-519-653-1498
Fax 1-519-653-1475

Dear Bob,

For your records, the identity of the "non-indicator" minerals in the batch of grains given to me October 5, 2001 is:

Sample DRX-1 - grain 15 - lithic fragment

Sample DRX-2 - grains 2,3,6,9,12,
13,14,17,20-23,28,29,31 - corundum
- grain 32 - Mg,Al,Cr-Ti magnetite (altered)

Sample 5294 - grains 1-5,12 - in plastic
grains 7,13 - pyrite
grains 8,21,24,27,34,37,38,
43,45,56,67,71 - apatite
grain 11 - grossular-almandine ss.
grains 15,30C,31,32,50,58,69,70 - sphene
grains 16,35 - amphibole
grain 29b - chalcopyrite
grain 36 - quartz
grain 60 - Mn ilmenite + phlogopite

Sincerely,

R. L. Barnett

November 22, 2001

Mr. Robert Dillman,

Ph 1-519-652-1498 Fax 1-519-652-1475

Dear Bob,

For your records, the purpose of this letter is provide information concerning the nature and fate of mineral grains for which analyses were not provided in the batch of grains given to me with your letter of November 15, 2001. These grains were identified using the EDS system on the microprobe during the course of mineral analyses.

Sample HD2 - grain 13 - perovskite

Sample 3-30 - grain 9 - quartz
grain 10 - sphene

Sample 3-32 - grain 1 - spessartine-almandine ss.
grains 3,6 - sphene

Sample 3-33 - grain 4 - apatite
grain 6 - lithic fragment
grain 10 - sphene

Sample 3-34 - grain 5 - ilmenite

Sample 3-39 - grains 3,5 - grossular-almandine ss.

Sample HD - grains 1-4 - Cu(S) chloride

Sample H2-10 - grain 7 - quartz

Sample H2-3 - grain 5 - melanite
12RX-3/5262 grain 11 - magnetite
grains 6,7,12, - Ti magnetite
grains 8,13,14, - perovskite
grains 15,16 - Ti magnetite + perovskite

Sample 6-22 - grains 1-3,13,14,16 - rutile
grains 4,5 - epidote
grains 7 - phlogopite-biotite ss.
grain 9 - magnetite
grains 10,11 - grossular-almandine ss.
grain 15 - Mn ilmenite

Sample MC-10 - grain 6 - zircon
grains 7,8,9,10 - grossular-almandine ss.

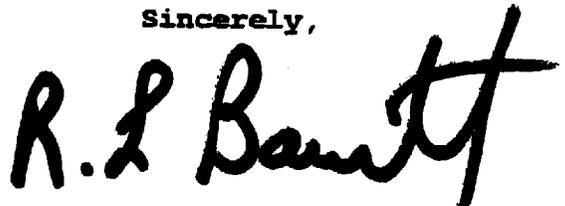

Sample XP-8 - grains 1,2,4 - grossular-almandine ss.

Sample ARY-4 - grains 1,4,5,6,7 - perovskite
grains - 2,3 - melanite

Sample CDF - grains 4,5 - quartz
grain 6 - ilmenite

Sample 5262 - grain 5 - serpentine
grain 6 - melanite

Sincerely,

R. L. Barnett

KIMBERLITE OR RELATED MINERALS: NO

DISTANCE ESTIMATE: 0 distance to black amphibole source.

TOTAL KIMBERLITE OR RELATED MINERALS:

OTHER MINERALS OF INTEREST: rusty coating on 5% of grains.

COMMENTS: occasional pink almandine - biotite - quartz composites (metamorphic)
Trace dark amphibole -biotite composite. Most black amphibole as subhedral or anhedral crystals, some twinned.
