INTRODUCTION

The Drouet Property straddles NTS map sheets 32G06 and 32G11, about 14 kilometers east of the Fenton gold deposit and 40 kilometers south of Chapais. The Fenton deposit, to the west, and the Joe Mann mine to the east. The Property is at the western end of the Caopatina sedimentary basin. The basin is bounded on its north side by the Opawica-Guercheville Fault, and on its south side by the Rémick Fault, which converge in the western part of the Property. The Opawica-Guercheville Fault may in part represent a remobilized syn-depositional growth fault, and represents a first-order regional structural control on gold mineralization (Fenton, Philibert, Lac Meston and Joe Mann deposits). On the north side of the fault a small (1.5 x 4 km) intrusive complex (Drouet Complex) is outlined by magnetics and diamond drilling. The diamond drill programs succeeded in demonstrating the presence of extensive shear zones with gold mineralization over a strike length of over 10 km. During 2003 and 2004 a geochemical survey consisting of 617 MMI, 11 till and 2 heavy mineral samples was conducted over portions of the property. Several MMI anomalies located south and east of the porphyry stock are identified. Additional work to identify the sources for these anomalies is required.

LOCATION, ACCESS AND TOPOGRAPHY

The project is located at 49.49° N latitude, 72.1° W longitude, within the Abitibi Mining Division, Quebec. The Drouet Property straddles NTS map sheets 32G06 and 32G11, about 14 kilometres east of the Fenton gold deposit and 40 kilometres south of Chapais. The claims are located in Drouet, Gradis and Druillettes tonwships (Figure 1).

Scale/Datum: NAD83

The topography of the project area is one of very low relief with elevation ranging from 345m to 390m. The area has numerous lakes and the project is cut by a major river, Rivière Opawica. There is very little outcrop in the area accounting for less than 1% of the surface area. Outcrop is most abundant in the northwestern part of the claims where there is thin overburden and some outcrop.

The project area has been extensively logged as is underlain by young pine trees and alder except in swampy areas where spruce and some poplar dominate.

Road access is good with a large logging main passing 15 km west of the project and good all weather roads accessing the main claim block. The nearest major centres are Chapais, located 40 km to the north and Chibougamou, located 70 km to the northeast. Both towns have a significant population, adequate power and a history of mining.

The Drouet area has a cold, continental type climate with a temperature range from 35°C to -40°C on average. The ground is snow covered generally from mid-November to the end of April with snow accumulations to over 2 m.

PROPERTY

The Drouet Project is comprised of 53 mining claims covering 1908 hectors. The claims are registered to Lake Shore Gold Corp (100%). A complete list of the claims is attached in Table 1.

PREVIOUS WORK

The area has been explored by SEREM in the 1960's, Falconbridge in the 1970's and Esso Minerals in the 1980's. These programs succeeded in demonstrating the presence of extensive shear zones with gold mineralization over a strike length of over 10 kilometres, but to date economic mineralization has not been found. An overburden drilling program by Esso

Minerals in 1986 (GM 44071, 44564), detected highly anomalous gold values from till samples and a follow up diamond drill program (GM 45676, 48402, 48055) encountered anomalous, but subeconomic gold mineralization, commonly associated with sheared and serecite altered quartz feldspar porphyry. Most drill holes, however, encountered some gold mineralization, including the following:

1.3 g/t Au/1.3 m (GD-34);

2.3 g/t Au/0.9 m (GD-24);

0.8 g/t Au/2.3 m (GD-15);

4.7 g/t Au/0.1 m (GD-4);

3.6 g/t Au/0.4 m (GD-33);

4.4 g/t Au/0.2 m (GD-32);

2.1 g/t Au/1.2 m (GD-38);

2.8 g/t Au/1.0 m (GD-38);

2.2 g/t Au/1.1 m (GD-37);

4.5 g/t Au/0.1 m (GD-29);

1.7 g/t Au/2.1 m (GD-18);

3.7 g/t Au/0.4 m (GD-6);

2.1 g/t Au/1.1 m (GD-22);

1.1 g/t Au/1.0 m (GD-25);

Very little drilling has been done on the north side of the main fault. The only drill hole in Esso's program (GD-27) encountered intercalated mafic volcanic and sediments cut by quartz-carbonate-feldspar-pyrite veins with anomalous gold (0.5 g/t over 1.5 metres). In addition, only limited drilling has been done at the eastern end of the Property, south of the Rémick Fault, where intense shearing and alteration is also associated with anomalous gold (1.0 g/t Au/1.6 metres, Esso DH LB-1).

In the eastern part of the property north of the Rémick Fault, SEREM in 1967 discovered massive concordant sulphides (90% pyrite-pyrrhotite-chalcopyrite-sphalerite over 1.2 metres) hosted by chlorite-altered tuffs above a quartz porphyry rhyolite dome (Lac Bernard-Ouest showing, drill hole F1). This appears to represent a VMS-type system. Mineralization is anomalous in Ag (13.7 g/t over 0.7 m), Au (0.34 g/t over 0.1 m) and Zn (0.2% over 0.1 m).

In 1985, prospecting by SOQUEM discovered 10.4 g/t gold in outcrop only 400 metres north of this showing on the west side of Lac Bernard (Roy, 1996). SOQUEM mapped an east-west trending felsic volcanic unit 600-1000 metres thick roughly coincident with a regionally extensive INPUT anomaly. This probably represents the western extension of the Lac des Vents volcanic complex. A drill hole collared about 1 kilometre north of the SEREM drill hole (1175-96-01) intersected mainly mafic flows, with one horizon of cherty rhyolite tuff containing about 10% pyrrhotite-pyrite.

GEOLOGICAL SETTING

REGIONAL GEOLOGY

The Abitibi Subprovince is the largest Archean greenstone belt of the Canadian Shield, and consists of east-west striking supracrustal strata and massive unfoliated intrusives covering an area of 300 by 700 km. The Abitibi greenstone belt has been divided into the northern and southern volcanic zones based on geology, geochemistry and geochronology (Dimroth et al, 1994; Chown et al, 1992).

The Northern volcanic zone is bounded to the south by the Destor Porcupine fault and to the north by high grade basement rocks and intrusives. The volcanic rocks of the northern volcanic zone have been divided into two arc construction cycles between 2730 Ma and 2720 Ma (Cycle 1) and 2720 Ma and 2705 Ma (Cycle 2) by Chown et al (1992). These cycles are

interpreted to consist of extensive subaqueous mafic volcanic plateaus or shield complexes underlying spatially restricted felsic arc edifices that consist dominantly of felsic volcanic and epiclastic rocks that initiate as marine edifices and gradually become emergent.

The core of the shield complexes in the northern Abitibi is marked by large mafic layered complexes, including the Lac Dore complex near Chibougamau and the (Bell Allard) pluton in the Mattagami area.

Linear belts of sedimentary rocks are a prominent aspect of the Abitibi belt. These restricted sedimentary basins have developed contemporaneously with the volcanic activity and develop along synorogenic faults and shear zones.

Chown et al (1998) define the northeastern corner of the Abitibi belt as the Chibougamau Caopatina region which they divide in to a northern segment around the Lac Dore pluton and a southern segment comprising the area around the Drouet claims. The southern segment consists of extensive tholeiitic basaltic rocks of the Obatogamau Formation. These rocks are overlain by localized felsic volcanic centres including the Lac Des Vents complex located east of the Drouet deposit. The youngest strata consist of sedimentary rocks of the Caopatina Formation, conglomerate, sandstone and argillite deposited in a 90 km long basin south of the Opawica fault.

The dominant regional structure recognized in the southern segment is the Opawica fault, a regional scale shear zone that extends from the northeast trending Lamarck fault in the west to the Grenville front in the east.

Polymetallic VMS deposits are associated with the local felsic volcanic centres in the Joutel and Mattagami areas. Orogenic lode gold deposits tend to be clustered along major crustal breaks marked by significant deformation and long linear sedimentary basins. The most

significant deposits in the northern Abitibi are associated with the Casa Berardi break (Casa Berardi, Douay and Discovery deposits), the Detour break (Detour Lake, Fenelon deposits) and the Opawica fault (Joe Mann). There are also a number of important copper gold vein deposits (Merrill, Copper Rand, Henderson Mines associated with the Lac Dore pluton in Chibougamau.

The Drouet property is at the western end of the Caopatina basin, a sedimentary basin containing lithologies ranging from coarse felsic conglomerates to thin-bedded distal turbidites. The basin is bounded on its north side by the Opawica-Guercheville Fault, and on its south side by the Rémick Fault, which converge in the western part of the Property. The area on the north side of the Opawica-Guercheville Fault is underlain mainly by Obatogamau Formation mafic volcanics with intercalated felsic tuffs, cut by gabbro sills, or chlorite-quartz schists within the deformation zones. Rocks south of the fault consist of turbidites and conglomerates in contact with basaltic volcanic rocks. The Opawica-Guercheville Fault may in part represent a remobilized syndepositional growth fault, and represents a first-order regional structural control on gold mineralization (Fenton, Philibert, Lac Meston and Joe Mann deposits).

The Drouet Property is about 14 kilometres east of the Fenton gold deposit and 40 kilometres south of Chapais. The Fenton deposit consists of strongly silicified, sheared basalt containing lenses of semi-massive and disseminated sulphides surrounded by an aureole with veinlets of pyrite, pyrrhotite and gold. It has a mineral inventory of 426,173 tonnes grading 4.66 g/t gold at a 2 g/t cut-off. The Fenton deposit is interpreted by TGW Resources as a synvolcanic deposit, with the nearby Opawica River layered complex as the subvolcanic heat source. Intersections with both zinc and gold are not uncommon (e.g. 4.16% Zn and 5.8 g/t gold over 1 m at Fenton East). The Joe Mann deposit is located 70 km east of Drouet. This deposit is a classic orogenic vein deposit currently being mined by Campbell Resources. Mineral reserves and resources are currently estimated at 1.68 M tonnes @ 0.326 opt gold.

On the north side of the fault a small (1.5 x 4 km) intrusive complex (Drouet Complex) is outlined by magnetics; drilling in this intrusion by Exploration Orbite in 1986 encountered various lithologies including K-feldspar granite and ferrogabbro. Numerous felsic porphyry dykes cut volcanic rocks in the vicinity of this stock. Mineralization, consisting of quartz veins with pyrite, arsenopyrite, chalcopyrite and gold, appears to be controlled in part by porphyry dyke contacts. Alteration ranges from chlorite-carbonate to sericite-paragonite-carbonate-pyrite.

PROPERTY GEOLOGY

The Drouet Project is located in the southern segment of the Chibougamau-Caopatina region in the northeastern corner of the Abitibi Greenstone Province. Previous work has defined two main stratigraphic units and a variety of intrusive rocks in the area (Tait and Chown, 1987; Lauziere and Chown, 1988). The oldest rocks are tholieiitic basalts of the Obatogamau Formation. These rocks are dominantly massive feldspar porphryritic flows. They underlie much of the north and western parts of the claim group. South of the basalts are dominantly sedimentary rocks, both intercalated with and overlying the basalts. These consist of greywacke with subordinate mudstone, siltstone and conglomerate. Tait and Chown (1987) also map a small area of quartz feldspar porphyry intruding both the basalts and the sedimentary rocks. Drilling by Esso Minerals in the 1980's suggests that the porphyry is much more extensive than mapped extending several km's to the east as small intrusives and dykes or sills.

WORK PERFORMED

The 2003-2004 exploration program was completed in two phases. The first phase consisted of a preliminary evaluation including minor soil sampling, rock sampling and prospecting. Preliminary work was completed by H. Marsden, J. Bradford, J. Young, M. Hocking, and J. Brown in June and August of 2003. The results from this survey suggested B

horizon soils analysed by MMI-B was successfully detecting gold mineralization in bedrock beneath glacially transported overburden. A second, more extensive program of soil sampling was completed in November, 2004 to cover the remainder of the western half of the property where drilling, till samples, outcrop and soil sampling all suggested the potential for significant gold mineralization. The results for the two programs are presented below.

MMI

Wide spaced soil lines were run over areas of known gold mineralization in drill holes to test the validity of using MMI-B selective leach analysis on B horizon soils to help locate mineralized zones beneath glacially transported overburden.

Eight-six MMI samples were collected during an initial survey in June 2003. Four north-south trending lines were sampled at 50 m intervals across the western half of the property. The survey was designed to test MMI response over known drill indicated gold mineralization. The survey successfully delineated anomalous gold values from threshold to very high values (7.7 ppb Au).

A further 158 MMI samples were collected between August 6th and August 9th 2003 adding lines adjacent lines with anomalous Au responses. Five pairs of adjacent lines 200 m apart were sampled at 50 m intervals along 5 km of strike. An additional 50 samples on four lines were completed on August 9th, 2003 west of Lac Bernard at the eastern end of the claim block.

In 2004, between October 17th and October 29th a further 373 soil samples were collected by P. Coulombe and S. Coulombe, contracted from Norman McBride. The samples were collected on north south lines to fill in the remainder of the western half of the property at 200m spacing. Lines were run north south using a hip chain and compass with stations located

by GPS. Samples were collected at 50 m intervals along the lines using an auger to select B horizon oxidized soil 10 cm beneath the base of the surface organics. Sample sites were marked in the field with orange flagging and an embossed aluminum tag. Lines diverged from ideal north south lines in order to avoid swampy areas and small lakes or creeks.

The survey was successful in delineating gold anomalies in the western part of the block in an area with known gold in till and gold in drill holes. Two lines in the central part of the property underlain by two drill holes with minor gold failed to detect any anomalies. The four lines in the eastern part of the claim block, with gold in till from RC holes, also failed to detect any anomalies.

Sampling on lines 488900E, 489100E, 491000E and 491200E indicated anomalies well above the threshold anomaly value of 0.2 ppb Au crossing from line to line in areas with known gold in drill holes. Some of the anomalies are directly associated with the drilled area, several anomalies are also present beyond any known drilling on lines 488900, and 489100E. Lines 488200E, 488900E and 490285E all indicate significant gold anomalies south of the historic drilling.

Till

Eleven blegg samples were taken on the west side of the property. A background value of 1-2 ppb gold was established, four anomalous values ranging from 4.4 to 24.6 ppb gold were observed. Two reshaped gold grains were recovered from a single heavy mineral sample, the corresponding blegg sample contained 4.8 ppb gold.

Rock

Twenty rock samples were collected during initial prospecting by J. Bradford, and J. Young on the west side of the property. Previous work has identified mineralization associated

with quartz veins controlled by the contacts of felsic porphyry dykes and chlorite-carbonate to sericite-paragonite-carbonate-pyrite. Fourteen samples of quartz-feldspar porphyritic leucotonalite rock, with variable sericite-silica-pyrite and iron carbonate-sericite-pyrite alteration, hosting pyrite-chalcopyrite bearing quartz veins were collected. Samples 108154 and 108172 returned gold values of 2000 ppb and 758ppb gold, the rest of the porphyry samples contain low values between 5 and 38 ppb gold. In addition, 2 sericite-schist and 4 variably altered chlorite-carbonate-pyrite mafic volcanic rocks contained minor gold values of less than 40 ppb. Two chip samples of dark-quartz veins hosted by felsic porphyry schist contained no significant metal values.

Seven samples were taken during a shoreline traverse of Lac Bernard on the east side of the property. Quartz veins with minor pyrite hosted by foliated, locally carbonate altered, mafic and felsic volcanic rocks contained no significant gold values.

CONCLUSIONS AND RECOMMENDATIONS

Historical and current exploration work on the property indicate the presence of wide spread anomalous gold mineralization. The current MMI soil geochemistry survey has outlined several anomalies to the south and east of the felsic Drouet intrusive complex. As these anomalies occur in several small clusters they should be investigated further by diamond drilling. A small geophysical survey may be required in the area to identify any conductors or structures that may aid in the targeting of drill holes.

LABORATORY SAMPLE LOG

)ject: 03 series
ename: LAKE SHORE GOLD - Henry Marsden - July 2003
tal Number of Samples in this Report = 6

Batch Number: 1600

Sample Number	Weight (kg)				Clasts >2.0 mm					Matrix <2.0 mm								Class
						Percentage				Distribution				Colour				
	Bulk Rec'd	Table Split	+2 mm Clasts	Table Feed	Size	V/S	GR	LS	OT	S/U	SD	ST	CY	Sand	Clay	Org		
0756	7.2	6.7	0.6	6.1	P	40	60	0	0	S	F	+	-	LOC	LOC	N		SAND + SILT

*Some samples prescreened to <7.0 mm in the field.

OVERBURDEN DRILLING MANAGEMENT LIMITED
GOLD GRAIN SUMMARY SHEET

Project: 03 series
Filename: LAKE SHORE GOLD - Henry Marsden - July 2003
Total Number of Samples in this Report = 6 Batch Number: 1600

Sample Number	Number of Visible Gold Grains				Nonmag HMC Weight (g) *	Calculated PPB Visible Gold in HMC			
	Total	Reshaped	Modified	Pristine		Total	Reshaped	Modified	Pristine
03-0756	7	4	1	2	24.4	7	6	0	1

* Calculated PPB Au based on assumed nonmagnetic HMC weight equivalent to 1/250th of the table feed.

OVERBURDEN DRILLING MANAGEMENT LIMITED

CERTIFICATE VO03023229

Project : L9500-Drovet

P.O. No:

This report is for 86 PULP samples submitted to our lab in Val d'Or, Quebec, Canada on 20-Jun-2003.

The following have access to data associated with this certificate:

HENRY MARSDEN

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
ME-MS10	MMI-B Leach - Precious Metals	ICP-MS

Drouet.

To: **LAKESHORE GOLD CORP.**
ATTN: HENRY MARSDEN
UNIT G, 1988 KINGSWAY ST
SUDBURY ON P3B 4J8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE VO03026896

Project : L95000

P.O. No:

This report is for 29 SOIL samples submitted to our lab in Val d'Or, Quebec, Canada on 14-Jul-2003.

The following have access to data associated with this certificate:

HENRY MARSDEN

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
LOG-24	Pulp Login - Rcd w/o Barcode

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Au-AA12	BLEG - 1 to 3 Kg bottle roll	AAS

Drouet.
Cuopatina.
