GEOCHIMIE DES SEDIMENTS DE RUISSEAU

REGION DE STE-CECILE-DE-WHITTON

Au cours de l'été 1971, la Société Québécoise d'Exploration Minière (SOQUEM) a effectué une campagne d'exploration géochimique sur un territoire d'environ 3 300 km² à la limite des Cantons de l'Est et de la Beauce (fig. 1). Environ 6 000 échantillons de sédiments de ruisseau ont été prélevés sur ce territoire. La SOQUEM a par la suite remis ces échantillons au Service de géochimie/géophysique du MER afin qu'il rende publics les résultats de ce levé.

Les échantillons furent analysés au Centre de recherches minérales en 1983 pour les éléments suivants: Cu, Zn, Pb, Ni, Co, Mn, Mo, Ag et U. La perte au feu (PF) fut aussi évaluée. Tous les éléments furent dosés par spectrophotométrie d'absorption atomique, sauf U qui fut dosé par fluorimétrie.

Les résultats sont présentés sous forme de liste ainsi que sur 9 cartes à l'échelle 1:125 000. Une dixième carte à la même échelle présente une synthèse des aires anomaies. Finalement, des cartes à l'échelle 1:50 000 localisent chacun des sites échantillonnés. Il n'y a pas eu de cartes géochimiques produites pour Ag. La raison en est que la limite de détection analytique pour cet élément est plus élevée que sa concentration réelle dans les sédiments de ruisseau de sorte qu'un pourcentage infime d'échantillons est anomal en Ag. Au lieu de présenter ces teneurs anomaies sur une carte, nous les présentons donc sous forme de tableau (tableau 1). De plus, il est à noter que le seuil analytique a changé à partir de l'échantillon # 86159: les numéros d'échantillons inférieurs à celui-ci ont un seuil analytique de 0,1 ppm en Ag tandis que les autres ont un seuil de 0,2 ppm.

Les histogrammes de distribution de chaque élément sauf Ag sont présentés à la figure 2, tandis que le tableau 2 donne les moyennes, écarts-types ainsi que les pourcentages d'échantillons dans chaque classe géochimique.

Tableau 1: Echantillons anomaux en Ag
