RAPPORT DES TRAVAUX D'EXPLORATION ÉTÉ-AUTOMNE 2000

PROPRIÉTÉ YASINSKI NORD PERMIS D'EXPLORATION MINIÈRE # 1404

SOMMAIRE

À la requête de Ressources Dianor inc., Géologica Groupe-Conseil Inc. a été mandaté pour superviser de la géophysique et un programme de forage carottier à diamant sur la propriété Yasinski Nord et sur une partie du permis d'exploration minière # 1404 localisés, dans la région de la Baie-James, Province de Québec ; soit à environ 540 kilomètres au nord de la ville de Matagami. Ces terrains sont détenus à 100% par Ressources Dianor Inc.

Les plus anciens travaux d'exploration connus datent de 1958 et couvrent le territoire contrôlé par Ressources Dianor inc. Des programmes régionaux ont été effectués par la suite et un intérêt grandissant s'est manifesté par un accroissement de l'activité minière au début des années 1990. Les travaux ont consisté en de la prospection, de la coupe de ligne, de la reconnaissance géologique, de la géophysique au sol et aéroportée ainsi que des sondages au diamant.

Les propriétés et le P.E.M. se localisent dans la sous-province géologique de La Grande. La région comprend un assemblage complexe de masses plutoniques et d'orthoigneiss au sein desquels se retrouvent plusieurs ceintures volcano-sédimentaires relativement étroites et d'âge Archéen. Des indices aurifères à haute teneur associés à des formations de fer et/ou à des zones de cisaillements porteurs de veines de quartz ont été découverts dans ces ceintures volcano-sédimentaires.

Les travaux d'exploration minière entrepris, par ressources Dianor, au cours de l'été-automne 2000 sur les propriétés Yasinski, Yasinski Nord et sur le P.E.M # 1404 ont permis de vérifier certaines cibles PP-résistivité localement associées à des indices de surface. Trois secteurs, où la quantité d'échantillons ont retourné des teneurs aurifères anormales, ont été découverts. Ils ont également permis d'établir des relations spatiales entre certains indices. Parmi les relations observées les trois suivantes semblent les plus importantes : 1) deux structures aurifères dont la longueur présumée est d'environ 2 km se poursuivent possiblement jusqu'à l'extrême est du P.E.M ; 2) le contact entre les basaltes amphibolitisés et la tonalite du Pluton d'Amisach Wat est propice à la découverte de minéralisations; 3) les coulées de basalte bréchifiées à l'est de l'indice Massé présentent un potentiel aurifère.

Les travaux récents complétés au cours de l'été et l'automne 2000 entre juin et octobre ont consistés en de la coupe de lignes complémentaire, un levé PP résistivité ainsi que dix (10) sondages carottier à diamant totalisant 1258 mètres forés sur des cibles géologiques et géophysiques correspondants aux zones Benoît Extension, Pierre, Giaro et Ékomiak localisées le long de la bordure est et sud de la propriété Yasinski Nord. Des échantillons (6) de carotte furent sélectionnés le long du sondage 1404-03 afin de compléter des descriptions pétrographiques et minéragraphique. Une révision de la procédure de préparation des échantillons fut complétée afin d'obtenir une meilleure fiabilité des analyses.

La géophysique PP-Résistivité (TDIP) s'est avérée utile pour déterminer la minéralisation aurifère en certains endroits et les extensions des contacts géologiques et des structures. Celle-ci

complétée au 50 mètre a permis de mieux caractériser les zones minéralisées au sein du couloir Benoît Extension et de reconnaître plusieurs cibles de forage ainsi que de faire ressortir les contacts géologiques, les structures principales et leurs orientations.

Neuf (9) des sondages sur dix (10) ont recoupé de la minéralisation aurifère. Ces sondages ont reconnu la minéralisation encaissée par un hôte intrusif porphyrique et alcalin. Le sondage 1404-17 a recoupé la zone minéralisée aurifère la plus significative avec 34,28 mètres à 0,76 g/t Au et 2,4 g/t Ag. Ce sondage a reconnu la zone Pierre et le couloir aurifère Benoît Extension sur une distance de 1,7 km et sur une largeur d'environ 100 mètres. L'étude pétrographique décrit la roche encaissante comme un porphyre de composition latitique monzonitique dont la matrice est intensément altérée par la dolomie, séricitisation intense ou une albitisation associée. Cet intrusif compétent et localement fracturé, bréchifié et cisailé offre un potentiel intéressant pour la mise en place de stockworks de veines et de veinules aurifères. Des zones de cisaillement encaissant des veines verticales et des lentilles de quartz boudinées furent aussi recoupées. La minéralisation est essentiellement de la pyrite, laquelle s'associe à l'altération de la matrice par le carbonate et la séricite. L'or, relativement abondant par endroits se présente en inclusion dans la pyrite le plus souvent mais aussi en gouttelette dans la pyrite et libre dans les silicates.

Il est recommandé de poursuivre la coupe de ligne, la géophysique, la cartographie, le décapage et le forage le long du couloir Benoît Extension, l'indice Giaro et de tester d'autres cibles géophysiques et/ou indices ailleurs sur le PEM.

Le potentiel pour la recherche des platinoïdes (PGE) demeure significatif vu la présence de nombreux intrusifs (dykes, plugs, sills) mafiques à ultramafiques sur le permis et dans les environs.

De plus, suite à un intérêt accru des sociétés d'exploration pour la recherche du diamant dans la région proximale de Weminji, il serait judicieux d'en évaluer le potentiel sur le PEM 1404 et les zones limitrophes. Des dykes mafiques de lamprophyres contenant des xénolithes d'environ 5 mètres d'épaisseur et reconnus sur 100 mètres présentent déjà un environnement favorable.

INTRODUCTION

Ce rapport fait suite à une campagne d'exploration effectuée au cours de l'été-automne 2000 par Ressources Dianor Inc. Cette campagne fut effectuée sur la propriété Yasinski Nord et sur une portion du Permis d'Exploration Minière (P.E.M.) # 1404, et comprenait un levé géophysique (PP Résistivité) au sol, du sondage au diamant, du décapage, de la coupe de lignes, de la cartographie et de l'échantillonnage. Géologica Groupe-Conseil Inc. fut mandaté pour superviser les travaux et compléter un rapport d'intégration des données.

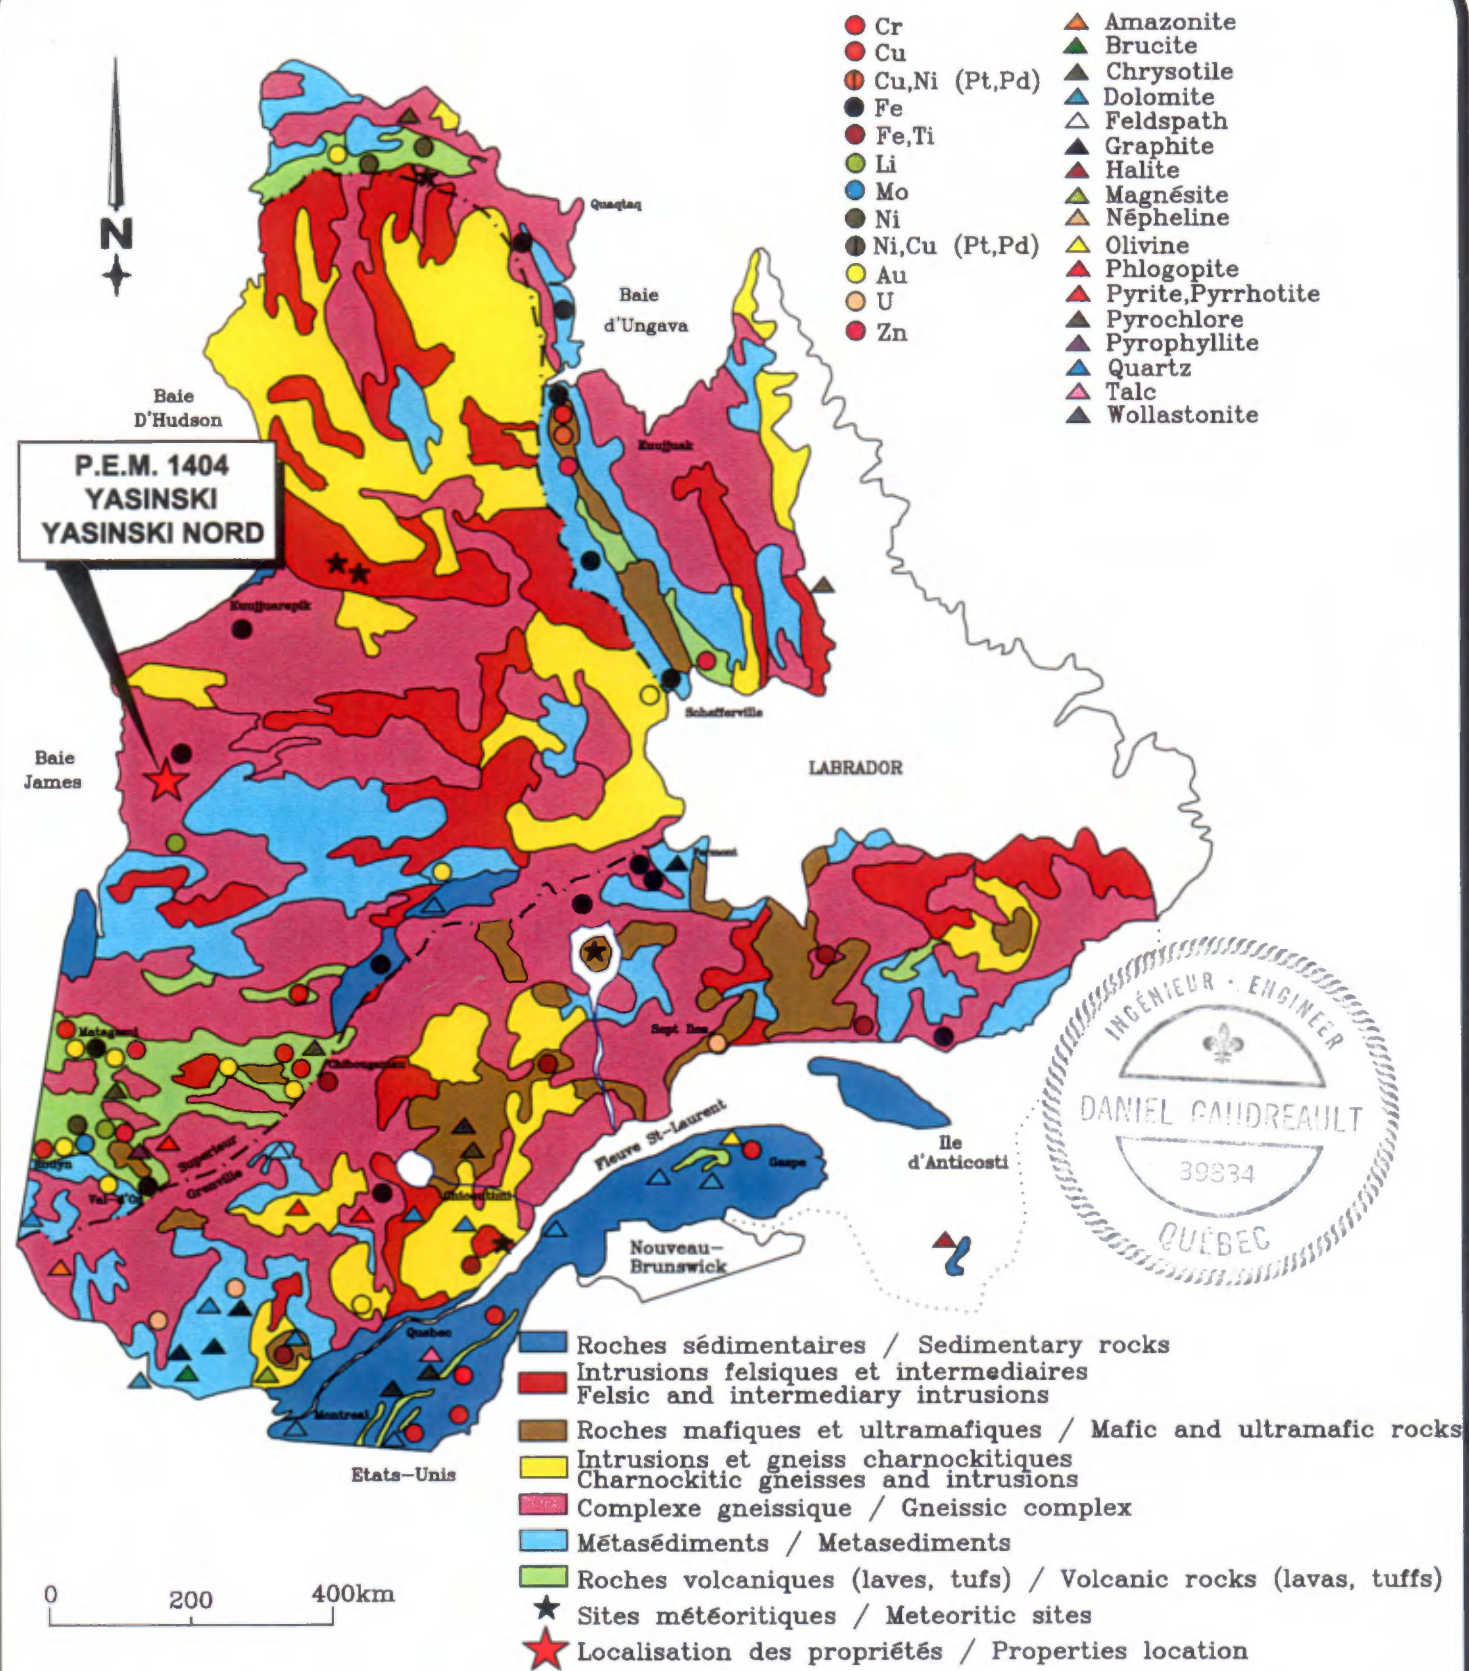

DESCRIPTION DE LA PROPRIÉTÉ

LOCALISATION ET ACCÈS

Les propriétés Yasinski, Yasinski Nord et le P.E.M. # 1404 sont localisés sur le feuillet SNRC 33F/06 et couvrent la partie ouest et nord du lac Menarik. Le centre géographique de ce permis est situé à la latitude 53° 23' et la longitude 77° 25'.

La bordure ouest du P.E.M. # 1404 est située à environ 4 km à l'est de la route de la Baie de James, et à 553 kilomètres au nord de la ville minière de Matagami, ou à 68 kilomètres au sud de la ville de Radisson. (fig. 1 et 2)

L'accès à la propriété s'effectue par une route tertiaire d'environ 10 km qui relie le camp du lac Menarik à l'indice Pierre et les autres indices adjacents à l'indice Pierre. De plus, l'accès peut s'effectuer par bateau via le lac Ekomiak et le lac Menarik, deux portages doivent être effectués pour atteindre la propriété. Un premier entre le lac Ekomiak et l'extrême ouest du lac Menarik; et un second, 2.5 km plus à l'est, au niveau d'un passage étroit du lac Menarik. Finalement, le permis est accessible par air via le lac Menarik.

TITRES MINIERS

Les propriétés Yasinski, Yasinski Nord, ainsi que le P.E.M. # 1404 sont détenus à 100 % par Ressources Dianor inc. Le P.E.M # 1404 a une superficie de 5059 hectares soit un bloc d'environ 7 km par 8 km. Le permis d'exploration a été acquis en 1998 et demeure valide jusqu'au 03 septembre 2003. Les propriétés Yasinski et Yasinski Nord sont localisées à l'intérieur du périmètre du P.E.M (fig. 3)

La propriété Yasinski est constituée de 34 claims miniers contigus totalisant une superficie de 542 hectares. Ce bloc de claims est centré sur la partie ouest du lac Menarik (fig. 3). Le tableau suivant donne la liste des claims ainsi que leur date d'expiration.

HYDROGRAPHIE ET TOPOGRAPHIE

La région étudiée se situe dans un bassin hydrographique qui se draine vers l'ouest dans la Baie-James. Le relief est généralement peu accentué à l'exception de quelques collines qui ont une dénivellation maximum de 50 m. Le secteur est faiblement boisé, un feu de forêt ayant dévasté la région au début des années 1990. En plus du lac Menarik, plusieurs petits ruisseaux et lacs sillonnent les propriétés assurant un approvisionnement en eau pour d'éventuels travaux de forages.

HISTORIQUE D'EXPLORATION

Tiré de Marc P. Banas, septembre 1998

La région de la Baie-James a été cartographiée une première fois à l'échelle 1 pouce = 8 miles par la Commission Géologique du Canada durant la période 1957-1959. Des cartes et rapports ont été publiés par Lee, Eade and Heywood (1959) et Eade (1966).

La compagnie Main Exploration a été le premier titulaire de permis à avoir effectué des travaux à proximité ou sur les propriétés Yasinski, Yasinski Nord et du P.E.M. # 1404. Durant la période de 1958 à 1960, la compagnie a effectué des travaux de prospection; de géophysique; de cartographie géologique ainsi que des tranchées. Ceux-ci ont établi un lien entre la présence de sulfures et l'emplacement d'intrusions

ultramafiques. Plusieurs sondages au diamant ont été implantés sur la propriété Yasinski près de la rive du lac Ménarik où des valeurs anormales en cuivre (> 1%) et en or (300 ppb) ont été obtenues dans des intrusifs felsiques porphyrique.

En 1972, la compagnie The Canadian Nickel Co. a effectué des travaux de cartographie ainsi que des levés radiométriques et magnétométriques aux abords des propriétés. Des sondages au diamant, ayant comme cible des contacts entre des roches métasédimentaires et des roches ultramafiques, ont été implantés. Des intersections ont retourné des valeurs atteignant 0,28 % Ni.

Dans les années 1973-1974, Le Ministère des Ressources Naturelles a effectué un levé de géochimie de ruisseaux couvrant un territoire de 5 855 km² incluant la région du lac Yasinski. Les échantillons ont été analysés pour le Cu, Zn, Pb, Ni, Co, Mn, V, Cr, Ba, Li, Mo, Cs, Sn, Ag et U.

En 1987, la compagnie Homestake Mineral Development a effectué des levés lithogéochimiques sélectifs dans la région du lac Yasinski. Les résultats ont identifié plusieurs zones anormales où les valeurs atteignaient 300 ppb Au; 176 ppb Pd et 35 ppb Pt (Données non disponible).

En 1990, Noranda Exploration a fait l'acquisition de P.E.M. dont certains englobaient l'extension ouest des ceintures de roches vertes localisées près du lac Menarik (propriété Yasinski). Noranda a effectué des études structurales détaillées qui ont montré que la minéralisation aurifère est reliée aux failles et à l'accumulation de fluides hydrothermaux le long des plans de foliation.

En 1995, Lang Vu compléta un levé géologique pour Mines Vauquelin sur la propriété Radisson.

Le Ministère des Ressources Naturelles vient de mettre à la disposition du public des cartes géologiques à l'échelle 1 : 50 000 pour les feuillets SNRC 33F/05 et 33F/06 basées sur des travaux effectués en 1996-1997.

En 1998, Jean Gouthier et al. compléta la géologie de la région du lac Esprit (SNRC 033F/05), RG 98-09.

En 1999, Marc Bannas et L. Melchioro complétèrent un rapport de travaux de reconnaissance des propriétés Baie James optionnées à Ressources Dianor Inc. La même année, P. Giaro compléta un rapport interne sur le secteur du PEM 1404. Par la suite, P. Lévesque de Géologica Groupe-Conseil Inc. compléta un rapport de travaux pour Dianor.

En mai 2000, P. Boileau compléta un rapport sur les levés géophysiques (Mag, TBF-EM, EMH et PP Résistivité) effectués sur le PEM 1404 pour Dianor. La même année, R. Girard de IOS Géosciences Inc. compléta des descriptions petrographiques et minéragraphiques de six échantillons de forage (1404-03) pour Ressources Dianor Inc.. En juin 2000, A.J. Beauregard de Géologica Groupe-Conseil Inc. compléta un rapport des travaux de terrain et de forages effectués en hiver 2000 pour Dianor sur le PEM 1404 à la Baie James.

GÉOLOGIE RÉGIONALE

Tiré de Gouthier et Al 1998.

La région étudiée se situe dans la partie centrale de la province géologique du Supérieur, plus précisément dans la sous-province de La Grande (fig. 4)

La sous-province de La grande se compose d'un assemblé de gneiss tonalitique ancien (10 %), d'une séquence volcano-sédimentaire (20 %) et de multiples intrusions de tonalite, de granite, d'ultramafique, de gabbro, et de lamprophyres.

Les roches du Groupe de Langelier sont les plus anciennes. Il s'agit de gneiss tonalitique et de tonalite à hornblende et biotite foliée à gneissique.

À base de la séquence volcano-sédimentaire, la Formation d'Apple se compose d'arénite quartzifère et de conglomérat monogénique à pyrite et uranium. Le Groupe de Yasinski, qui surmonte la Formation d'Apple, se compose principalement de basaltes et d'andésites intercalés de bandes de formations de fer, de grès, de conglomérats et de volcanites felsiques. Les volcanites du Groupe de Yasinski sont recouvertes par les grès et les conglomérats polymigtes de la Formation Ekomiak. Les roches volcaniques et sédimentaires se répartissent en plusieurs bandes kilométriques, séparées par des roches du Complexe de Langelier, par des failles et par des tonalites plus jeunes.

Après la première phase de déformation, l'intrusion de Ducan et le pluton d'Amissach Wat ont été mis en place suivis par le Complexe de Menarik et des Pyroxenites de la baie Chapus. Finalement, le Pluton de Tipitipisu, la Syénite du lac Bruce, le Granite du lac Taylor et des plutons associés à des pegmatites se sont mis en place.

Cinq phases de déformation ont successivement affectées une partie ou l'ensemble des roches de la région. Puis, toutes ces roches ont été recoupées par trois réseaux de diabase Protérozoïques.

Plusieurs indices de métaux de base du type sulfures volcanogènes et magmatiques (chrome et platine), ainsi que des indices aurifères et cuprifères liés à des zones de cisaillement et à des intrusions felsiques porphyriques, ont été identifiés dans la région de la Baie-James.

EXPLORATION MINIÈRE ET GÉOLOGIE ÉCONOMIQUE DE LA RÉGION DE LA BAIE-JAMES

Tiré de Marc P. Banas, septembre 1998

Au cours de la plus récente vague d'exploration minière au début des années 1990, plusieurs compagnies minières juniors ont obtenu des résultats prometteurs avec la découverte d'indices à forte teneur. Cette activité a attiré plusieurs compagnies minières productrices dans la région, notamment Noranda et American Barrick.

Ces découvertes peuvent être attribuées en partie à l'adaptation de méthodes géophysiques et géochimiques aux conditions particulières de la région des basses terres de la Baie-James. La présence d'arsenic, qui est fréquemment associé à l'or, produit souvent des anomalies dans les sols et les sédiments de fond de lac. À l'échelle régionale, les anomalies magnétiques bien marquées sont souvent causées par des niveaux de formation de fer auxquels des minéralisations aurifères peuvent être associées.

De récentes découvertes au sein de nouveaux contextes géologiques ont accru le potentiel économique de cette région, notamment les indices de métaux précieux et de métaux de bases associés à des zones de cisaillements majeures ainsi que les minéralisations de type porphyre.

L'investissement en exploration minière sur l'ensemble du territoire de la Baie-James au cours de l'année 1997 a été de 9,25 millions de dollars. Cette somme inclut un total de 2 millions de dollars d'aide financière du Gouvernement du Québec par l'entremise de son Programme d'Assistance à l'Exploration Minière. Finalement, un total de 44 885 mètres de forage au diamant a été implanté sur 48 projets.

* Information sur l'exploration obtenue de - Rapport sur l'activité de l'exploration minière au Québec en 1997 – MRNQ

GÉOLOGIE DE LA PROPRIÉTÉ

Sur la propriété les lithologies se présentent en bandes plus ou moins régulières, orientées est-nord-est. Cependant, ces bandes ont été découpées par des failles orientées

N060 à N080. Elles sont également affectées par des plis parasites aux plis régionaux et par des plis d'entraînement associés à des zones de cisaillement (fig. 5 et 5a).

Intrusion felsique à phénocristaux de feldspath (Monzonite) (I2F)

Ces intrusions ont des dimensions variables. Elles sont observées sous forme de dykes métriques; d'intrusions plus ou moins circulaires de 50 à 200 m de diamètre et d'un sill de 300 m épaisseur sur plus de 1500 m de longueur. Ces intrusions prennent place dans toutes les formations.

Ces intrusions sont de couleur beige jaunâtre en patine et rose verdâtre en cassure fraîche. Elles se composent de 50 à 60 % de feldspath hypidiomorphes à idiomorphes de 1 à 2 mm; de 20 % de minéraux mélanocrates intergranulaires et de 1 à 10 % de cristaux de quartz xénomorphes de 0.5 à 1.5 mm. Les phénocristaux de feldspath sont hypidiomorphes à idiomorphes. Ils représentent en moyenne 10 % de l'ensemble de la roche. Leurs dimensions varient de 0.5 à 1.5 cm. mais peuvent atteindre 2.5 cm à la base de l'intrusion où des textures de cumulat sont observables. Des xénolites de 1 à 15 cm sont également observables près des contacts. Finalement, ces intrusions sont localement faiblement magnétiques.

Ces intrusions sont discordantes. Toutefois, plusieurs sills et dykes ont été injectés à partir de ces intrusions. Ils sont rarement cartographiables car leur épaisseur est généralement inférieure à 10 m. Ces dykes témoignent très nettement que ces intrusions se sont mises en places avant ou pendant la dernière phase de déformation. Les contacts de ces intrusions sont soulignés par une très forte densité de dykes sur leur pourtour.

Intrusion felsique (I1)

Ces intrusions ont été observées sous forme de dykes métriques et en une petite intrusion d'un maximum 200 m de diamètre. Cette dernière intrusion est observable sur la

ligne 16+00 O à 1+50 N. Les contacts sont nets et peu foliés. Il est possible que ces intrusions soient en réalité des laves dacitiques.

Ces intrusions sont de couleur blanche en patine et vert translucide en cassure fraîche. Ils se composent d'un assemblage quartzofeldspathique finement grenu avec 20 % de cristaux de plagioclase pouvant atteindre 1.0 mm.

Gabbro (I3A)

Les gabbros observés sont sous forme de filon-couches comagmatiques de 5 à 25 m d'épaisseur au sein des basaltes. Dans certains cas, ces gabbros peuvent être des coulées massives. Les contacts avec les unités adjacentes sont généralement nets et peu foliés.

Ces gabbros ont une patine dont la couleur varie de vert à beige. En cassure fraîche, ils sont de couleur noir jaunâtre. Ils se composent d'environ 60 % de pyroxènes de 0.5 à 2.0 mm et de 40 % de plagioclases ont de 0.25 à 1.0 mm de diamètre. Les pyroxènes forment parfois des gloméroprophyres pouvant atteindre 8 mm de diamètre.

Dyke de diabase et/ou lamprophyre (I3B-I3O)

Des dykes de diabase ont été observés à plusieurs endroits sur la propriété. Ils ont généralement entre 0.2 et 8.0 m d'épaisseur mais l'un d'eux atteint 30 m d'épaisseur. Ils sont pratiquement toujours orientés N340/90, plus ou moins 10°. Les contacts sont nets et droits. Ces dykes n'ont pas été affectés par la déformation.

Ces dykes sont de couleur rouille en patine et noir en cassure fraîche. Ils se composent de 0 à 5% de plagioclases tabulaires de 1 à 10 mm baignant dans une matrice aphanitique fortement magnétique. Ils contiennent également de traces à localement 3 % de pyrite.

Dykes de hornblendite (I4A)

Cette lithologie fut observée un peu partout dans la région étudiée. Elle se présente sous forme de dykes et de filon-couches métriques. Ces intrusions n'ont pas d'orientation constante. Ils semblent s'être mis en places dans des zones de faiblesses de la roche après la dernière période de déformation car ils ne sont jamais déformés.

Cette roche, non magnétique, est de couleur gris fer en patine et gris pâle en surface fraîche. Elle se compose de 60 à 70 % d'amphiboles de 0.25 mm de section par 0.5 à 2.0 mm et de 30 à 40 % de plagioclases inférieurs à 0.5 mm. Ces intrusions contiennent de 0 à 5 % de xénolites de 1 à 20 cm. Ces xénolites sont de différentes compositions. Les deux plus fréquentes sont des roches ultramafiques très talqueuses et des roches granitiques de couleur blanches.

Basalte (V3A)

Les basaltes font partie de la Formation de Yasinski. Ils sont observés un peu partout dans la région étudiée. Ils forment deux assemblages distincts. Le premier est exclusivement constitué de basaltes massifs, coussinés et bréchiques; et de gabbro comagmatique. Cet assemblage s'observe en deux masses. Une au nord-ouest de la région étudiée, la seconde dans la partie centrale. Le deuxième assemblage est constitué de basaltes, coussinés et massifs; de gabbro et d'horizons métriques de tufs dacitiques. Cet assemblage forme un horizon de 30 à 50 mètres d'épaisseur qui semble former un pli au centre de la région étudiée.

Les basaltes sont vert pâle en patine et vert moyen en surface fraîche. Ils sont généralement aphanitiques et présentent des textures coussinées et bréchiques. La dimension des coussins varie de 0.3 m à 1.5 m en moyenne. Ils sont généralement fortement étirés. Les bordures sont inférieures à 1.0 cm. Les coulées bréchiques sont généralement fortement déformées et fréquemment injectées de veines de quartz

discontinues. L'altération la plus fréquente et diagnostique des basaltes est l'épidotisation.

Conglomérat polygénique (S4D) de Yasinski

Ce conglomérat fait parti de la Groupe de Yasinski. Il se distingue de celui de la Formation d'Ekomiak par sa forte proportion de fragments de roches mafiques et par son association directe avec une formation de fer. De plus, il est toujours surmonté d'un chert contenant en moyenne 10 % de pyrite. Le conglomérat ne semble pas avoir une épaisseur supérieure à 10 m.

Le conglomérat est de couleur verdâtre en patine et vert en cassure fraîche. Il se compose de 60 à 70 % de fragments de basaltes et de gabbro de 0.5 à 40 cm; de 10 à 15 % de fragments granitiques de 0.5 à 25 cm; de 5 à 10 % de fragments de formation de fer de 1 à 10 cm et de 5 % de fragments de tufs dacitiques.

Conglomérat polygénique (S4D) d'Ékomiak

Ce conglomérat fait partie de la Formation d'Ekomiak. Il se présente en bancs métriques avec des niveaux gréseux de 0.5 à 1.0 m qui sont fréquemment lités et ou laminés.

Le conglomérat est constitué à 40 % de fragments arrondis donc la dimension varie de 1 à 10 cm en moyenne. Toutefois, des fragments atteignant 25 cm et plus rarement 45 cm de diamètre ont été observés. Plus de 90 % des fragments sont de composition granitique. Des fragments de formation de fer, de quartz, de volcanique mafiques et de gabbro ont également été observés. La fraction primaire du conglomérat est de couleur gris-vert. Elle est très riche en quartz et en feldspath. La matrice est constituée de boue.

Grès lithique (S3)

Ces grès font partie de la Formation d'Ekomiak. Ils se présentent en bancs massifs, d'épaisseur métriques.

Ces grès sont de couleur gris en patine et gris vert en cassure fraîche. La granulométrie varie de fine à grossière. Cette variation est observable à l'intérieur d'un banc et d'un banc à l'autre. La composition de ces grès est variable.

Des passages conglomératiques ont localement, été observé dans le grès. Ces passages contiennent entre 5 et 15 % de fragments arrondis de 0.4 à 2.0 cm. Ils s'agit de fragments granitiques, de formation de fer, de cherts et plus rarement mafiques.

Sédiment lithique lité (S3D LM)

Ces sédiments lithiques lités font vraisemblablement partie de la Formation d'Ekomiak.

Ils sont de couleur beige rosé à verdâtre en patine et de différente teinte de vert et de rouge en cassure fraîche. La granulométrie varie de fine à aphanitique. Ces sédiments ont une composition qui se rapproche fréquemment du chert, mais avec des quantités variables de quartz et de feldspath. La variation de couleur est due à un apport variable en hématite, silice et/ou chlorite.

Le litage est très caractéristique de cette lithologie. Les lits ont de 1 à 10 cm d'épaisseur. Lorsqu'ils ne sont pas déformés, il est possible d'observer des lamines.

Ces sédiments sont fréquemment intercalés d'horizons mafiques de 30 à 40 cm et de formations de fer généralement inférieures à 1.0 m.

Tuf dacitique (V1)

Ces tufs forment des horizons de 0.3 à 3.0 m d'épaisseur, atteignant localement 15.0 m. Ils ont été observés en association avec des gabbros et des basaltes du Groupe de Yasinski.

Les tufs ont une couleur blanche en patine et une couleur verte translucide en cassure fraîche. Ils sont aphanitiques et non magnétiques. La composition semble dacitique. Ils présentent localement une lamination inférieure à 1 mm.

Formation de fer (S9)

Les formations de fer sont courantes sur la propriété. Elles sont observés autant dans la Formation d'Ekomiak que dans le Groupe de Yasinski. Elles forment généralement des horizons de 0.10 à 1.50 m d'épaisseur, mais elles peuvent localement atteindre 10.0 à 20.0 m. Il est possible que les épaisseurs apparentes supérieures à 10 m soient dues à des plis. À l'exception de quelques horizons, les formations de fer sont peu extensives et extrêmement boudinées.

Les formations de fer sont caractérisées par des lits de chert noir très magnétique. Les lits ont entre 0.5 et 15 cm d'épaisseur. Des laminés de chert blanc inférieurs à 1 mm sont fréquemment observés à l'intérieur des lits de chert noir. Une quantité très variable de 0 à 50 % de tufs ou de sédiments est observée entre les lits de formations de fer

L'horizon de formation de fer qui est associé aux conglomérats de Yasinski et au chert pyriteux est presque exclusivement constitué de magnétite.

GÉOLOGIE STRUCTURALE

Aucun pli régional n'a pu être défini au cours de la cartographie. Toutefois, il est évident que les lithologies ont été très fortement plissées. Ces plis semblent avoir deux

origines soit des plis parasites aux plis régionaux ou des plis d'entraînement associés à des zones de cisaillement. L'amplitude de ces plis varie entre 1 m à plus de 100 m. De façon générale, la charnière de ces plis est orientée W-SW avec une plongée variant de 50 à 75° en moyenne.

La foliation a une attitude moyenne W-WS avec des pendages variant de 60 à 90°. La plupart des zones de cisaillement et de fracturation sont orientées N060 à N080 avec un déplacement senestre (fig. 5). Plusieurs de ces zones sont visibles sur les photos aériennes. Elles peuvent facilement être suivies sur quelques kilomètres. À ces zones se conjuguent fréquemment des systèmes de veines de quartz en extension orientées N320 à N010.

MÉTAMORPHISME

Le niveau de métamorphisme de la région cartographiée est du faciès amphibolite inférieur. Sur le terrain, ce faciès est caractérisé par la dureté élevée; la couleur plutôt foncée des lithologies mafiques; et par l'absence de calcite et de chlorite sur la plupart des affleurements visités.

GÉOLOGIE ÉCONOMIQUE

Au cours des travaux d'exploration de 1998 à 2000, plusieurs indices aurifères furent découverts sur les propriétés. La figure 6 présente la localisation des différents indices et des secteurs anomaux de la région étudiée.

INDICE MASSÉ (L19+65 W; ST 3+10 N)

L'indice Massé est caractérisé par une veine de quartz de 5 à 10 cm de largeur contenant de l'or visible. Cette veine de quartz est contenue dans une coulée bréchique fortement déformée de 1 à 2 m de largeur. L'or visible (0,5 %) est observé en petites

paillettes de 1 à 3 mm associées à des géodes et en placages dans les fractures. Plusieurs échantillons furent récoltés sur cette veine. Les teneurs en or varient de quelques g/t à près de 2000 g/t Au.

Dans le secteur de l'indice Massé, il y a plusieurs autres coulées bréchiques contenant des veines de quartz du même type que celle décrite ci-dessus. De tous les échantillons récoltés dans les veines de ce secteurs, 6 ont retourné une teneur supérieure à 243 ppb Au. Ces valeurs proviennent de zones stratigraphiquement au-dessus et en dessous ainsi que latéralement à l'indice Massé. Ils démontrent nettement que le secteur est très anomal en or.

INDICE BENOÎT (L 9+00 W; ST 3 +30 S)

L'indice Benoît est une zone de fracturation dont l'épaisseur varie entre 2.0 et 4.0 m. Cette zone de fracturation est orientée N080 avec une pendage qui varie de 45 à 60⁰. Elle est injectée d'environ 10 % de veines de quartz. Ces veines ont une épaisseur qui varie de 2 à 30 cm. Ce sont les veines qui retournent les meilleures valeurs aurifères soit des teneurs variant de 0.22 à 8.26 g/t Au.

Les épontes des veines de quartz sont généralement fortement silicifiées et carbonatisées. Elles contiennent de 1 à 5 % de pyrite disséminée. De façon général, ce faciès d'altération est anomal en or avec des teneurs pouvant atteindre 0.5 g/t Au.

Plusieurs autres veines et roche hôte altérée du secteur ont retourné des teneurs anormales. Elles sont isolées et ne sont pas directement associées à la zone de fracturation de l'indice. Toutefois, elles démontrent que le système aurifère est bien développé dans le secteur.

SECTEUR BENOÎT EXTENSION

Ce secteur à environ 800 m de longueur et correspond à l'extension est de l'indice Benoît. Il est caractérisé par une série de veines de quartz de 5 à 30 cm de largeur associée à des zones d'altération métriques. Ces zones ont la même orientation que l'indice Benoît. Les veines de ce secteur ont retourné des teneurs atteignant 36.5 g/t Au.

Il semble très probable que, dans ce secteur, la zone de fracturation passant par l'indice Benoît n'a pas été mise à jour ou que la zone de fracturation n'est pas bien développée en surface.

INDICE GORDIE (L11+23 W; ST 5 +07 S)

Cet indice a retourné des teneurs variant de 0.9 à 12.7 g/t Au. Il est caractérisé par une zone de fracturation de 2.5 m de largeur orientée N080/90. La portion centrale de cette zone (1.0 m) contient 50 % de veines de quartz de 10 à 25 cm d'épaisseur. Le quartz est blanc et localement enfumé. Il contient de 2 à 40 % de pyrite. Cette dernière se présente en amas de 0.5 à 3.0 cm. Elle est généralement idiomorphe et varie de 0.1 à 4.0 mm de côté. La roche hôte est un sédiment lithique ou un basalte fortement silicifié. Elle contient de 1 à 5 % de pyrite idiomorphe de 0.2 à 2.0 mm.

Comme pour l'indice Benoît, plusieurs autres veines et roches hôtes du secteur ont retourné des teneurs anormales. Elles sont également isolées et ne sont pas directement associées à la zones de fracturation. Toutefois, elles démontrent également que le système aurifère est bien développé dans le secteur.

INDICE WILL (L13+98 W; ST 5 +10 S)

Cet indice est localisé directement au contact de l'intrusion granitique à phénocristaux de feldspath. Il est également localisé sur la même zone de fracturation que l'indice Gordie qui se trouve 275 m plus à l'est.

Cette zone de fracturation est visible sur une largeur de deux mètres. Elle est orientée N078, avec un pendage qui semble verticale. Elle est caractérisée par l'injection de 50 % de veines de quartz dont l'épaisseur varie de 5 à 20 cm. Le quartz est blanc. Il contient entre 5 et 10 % de pyrite, 1 % de chalcopryrite et des traces de galène. La pyrite est en amas et en veinules inférieurs à 5 mm. La chalcopryrite est distribuée au pourtour des amas de pyrite. Elle est également observée en plages isolées. La galène est directement associée à la chalcopryrite.

Les épontes des veines de quartz sont fortement chloritisées et faiblement séricitisées. Elles contiennent de 5 à 15 % de pyrite disséminée de 0.1 et 1.5 mm. Cette pyrite est hypidiomorphe.

Des teneurs variant de 0.8 à 7.5 g/t Au ont été obtenues des veines de quartz. Les épontes des veines ont également retourné des teneurs économiques pouvant atteindre 12.0 g/t Au.

D'autres veines de quartz ou zones de cisaillement du secteur ont retourné des teneurs aurifères pouvant atteindre 2.7 g/t Au.

INDICE PIERRE

Cet indice est caractérisé par un réseau de veines et veinules de quartz contenu dans une intrusion felsique à phénocristaux de feldspath. L'enveloppe de ce réseau de veines et veinules semble être orientée N214/80 et est située près du contact de l'intrusion. La largeur minimum de cette enveloppe est de 20 m. Il est à noter que les contacts de cette zone n'ont pu être observés.

Les veines et veinules ont une largeur de 0.3 à 25.0 cm. Elle contiennent entre 1 et 20 % de pyrite idiomorphe et disséminée. Cette pyrite a de 0.5 à 1.5 mm de côté. Les épontes des veines de quartz sont fortement silicifiées et carbonatisées. Elles contiennent de 1 à 10 % de pyrite disséminée de 0.5 à 1.5 mm de côté. Cette minéralisation a retourné

des teneurs anormales variant de 0.37 g/t Au à 2.82 g/t Au. Ces valeurs sont directement associées aux veines de quartz qui ont provoqué une silicification et une carbonatation de leurs épontes.

INDICE DE L'AUTOBUS

Cet indice est caractérisé par une veine de quartz de 2 m d'épaisseur orientée N245 qui a été suivie sur plus de 300 m . Cette veine s'est mise en place au contact entre des basaltes amphibolitisés et la tonalite du Pluton d'Amisach Wat. Cette veine et ses épontes ont retourné des teneurs variant de traces à 1.6 g/t Au.

SECTEUR ANOMAL PASCALE (L 1+00 W; ST 0+50 N)

Ce secteur inclut une série d'échantillons (11) qui ont titrés entre 0.4 g/t Au à près de 37.0 g/t Au. Ces échantillons proviennent de plusieurs types de minéralisation qui semblent ne pas être associés les uns avec les autres. À l'exception de la veine de quartz et galène (75 m), les zones minéralisées de ce secteur semblent peu continues.

Toutefois, il en va de même dans les environs de certains autres indices de la propriété où la continuité de la minéralisation ne peut pas être mise en doute. Il semble donc fort probable que la structure porteuse ou maîtresse de ce secteur n'a pas encore été découverte.

SECTEUR ANOMAL DAVID

Ce secteur anomal est caractérisé par une série de veines de quartz de 0.1 à 0.3 m de largeur retournant des teneurs variant de 0.5 à plus de 66.0 g/t Au. Ces veines ont des orientations variables mais la plus fréquente est N060.

L'auteur n'a pas visité tous les sites où des échantillons ont retourné des teneurs aurifères. Toutefois, les échantillons 42345 à 42348 ont été récoltés sur des veines de

quartz associées à une zone de fracturation et d'altération faible orientée approximativement N065. Cette zone à 15 m de largeur. Elle est caractérisée par une altération en chlorite, carbonate et hématite. Cette zone d'altération est similaire à celle observée dans le secteur Benoît extension. Il est fort probable qu'il y est une zone de fracturation, au sud-est de l'affleurement.

Plusieurs autres échantillons plus ou moins isolés ont retourné des teneurs aurifères anormales à nettement économiques.

Deux échantillons ont retourné des teneurs de 20.3 g/t Au et 37.6 g/t Au. Ils sont exactement au même contact structural que les indices Gordie et Will donc cette structure est porteuse de teneur aurifère sur plus de 500 m.

TRAVAUX RÉCENTS

Au cours de l'été-automne 2000, entre juin et octobre, une grille de lignes coupées complémentaires fut complétée suivie d'un levé géophysique (PP Résistivité). Une campagne de sondage au diamant (1 258 mètres) fût ensuite réalisée. Ce rapport rend compte des résultats de ces travaux récents.

GRILLE DE LIGNES COUPÉES COMPLÉMENTAIRES

Une grille de 40,78 km quadrillée au 50 mètres fût rafraîchie dans la partie centre-sud du PEM à proximité de l'indice Pierre afin de permettre le levé géophysique et la cartographie détaillée sur les sites décapés.

DÉCAPAGES MÉCANIQUES

Le décapage mécanique (indices Pierre, Pierre Sud, Pierre Ouest, Pierre SE, Shear Ékomiak, indice Giaro, etc.) fût réalisé par la compagnie Lemiro. L'emphase fût mis sur

les extensions de la zone Pierre. Quatorze (14) sites ont été dénudés afin de reconnaître les extensions minéralisées des zones connues ainsi que des anomalies PP Résistivités sub-affleurantes. Au total, 4250 mètres carrés furent décapés. Six des quatorze sites sont avoisinant de la zone « 450 » (L 8+50W / L 4+50 S).

CARTOGRAPHIE DÉTAILLÉE

Cette cartographie détaillée fût concentrée surtout sur les indices décapés et les zones minéralisées (voir figures et plans en annexes).

CARTOGRAPHIE DE RECONNAISSANCE

Quoique locale et non systématique vu le volume de travaux à effectuer sur les indices minéralisés aurifères et décapés, celle-ci nous a permis de reconnaître les dykes mafiques et ultramafiques avec une plus grande définition par la géochimie et la pétrographie. Ces dykes et brèches furent échantillonnés pour analyser les PGE et le diamant par dissolution caustique.

LEVÉ GÉOPHYSIQUE (QUANTEC) – « GRADIENT ARRAY REAL SECTION » (TDIP / PP RÉSISTIVITÉ DU DOMAINE TEMPS)

Ce levé fût complété afin de reconnaître des signatures favorables de chargeabilité et de résistivité associées à des zones aurifères potentielles en se fondant sur les contrastes des propriétés physiques. Un total de 40,78 km fût couvert en 13 jours. Les lectures furent notées à tous les 12,5 mètres et 15 sections orientées E-W et N-S furent complétées en utilisant un récepteur Iris Elrec – 10 (canaux); un transmetteur Phoenix IPT-1 (15 kW/600-2400 V output) et une alimentation par génératrice Phoenix MG-3 (2,5 kVA, 60 V, 3 phases, 400 Hz) Honda de 5.5 HP.

Cinq des dix sondages coïncident à des cibles PP Résistivité (basse résistivité et chargeabilité de moyenne à forte localement).

Les faits saillants du relevé sont les suivants :

- 1) Les sections verticales et les plans horizontaux présentent la résistance et la polarisation de façon variable et hétérogène montrant plusieurs zones subparallèles. Ces zones correspondraient à un corridor de déformation d'environ 400 mètres de large reliant la zone Benoît dans la partie nord et le cisaillement Ékomiak dans la partie sud.
- 2) La zone Pierre correspondrait quand à elle à une signature géophysique plus complexe et étendue que prévue incluant l'extension Pierre Ouest (75-100 mètres vers l'ouest) ainsi que l'extension ouest du cisaillement Ékomiak (75 mètres au SE de l'indice Pierre) et l'extension sud de l'indice Pierre (25-50 mètres au sud reconnue par le sondage 1404-03).
- 3) La plupart des anomalies liées aux zones aurifères encaissées au sein de la monzonite ou aux cisaillements encaissant des sulfures disséminées, semi-massifs et massifs présentent aussi des extensions en profondeur.

ÉCHANTILLONNAGE EN CANNELURE ET ÉCHANTILLONNAGE PONCTUEL (ÉCHANTILLON CHOISI)

L'indice Giaro fût échantillonné par échantillons choisis lors de la campagne de prospection de 1999 révélant 20,4 et 30,6 g/t Au. Suite au décapage, sept échantillons en cannelure furent prélevés sur 25 mètres de long et 8 mètres de largeur. Les teneurs varient de 1,4 g/t Au et 44,94 g/t Au. Ce site est caractérisé par plusieurs cisaillements et fractures orientés N40°E à N80°E localement injectés de veines et veinules de quartz aurifère.

L'indice Pierre-extension ouest situé à environ 75 mètres à l'ouest de l'indice Pierre fût l'objet de 19 échantillons choisis (grab samples). Des teneurs atteignant 12,75 et 25,11 g/t Au associés à des veines et veinules de quartz pyritisées et altérées en silice et pyritisées.

Située dans la partie SE à la limite de la zone décapée, un échantillon choisi prélevé sur une petite veinule de quartz-carbonate a révélé 769,2 g/t Au (# 23062). Cette zone est associée au corridor (N110°E) aurifère fracturé de la monzonite et relie l'indice Pierre Ouest et Pierre sud. L'or visible se présente sous forme de petits nuages de grains fins et disséminés à proximité d'une fracture N-S. Ce corridor d'environ 3-10 mètres d'épaisseur par 175 mètres de longueur semble relier le cisaillement Ékomiak au stockwork minéralisé de l'extension Pierre Sud.

L'indice Cisaillement Ékomiak fût échantillonné par 12 échantillons choisis (« grab sample ») et huit échantillons de rainure prélevés sur une zone décapée d'environ 25 mètres de long et de 3 à 5 mètres de large. La meilleure teneur obtenue a révélé 61,5 g/t Au sur 0,65 mètres. Des échantillons choisis y avaient révélé 7,5 et 16,6 g/t Au en 1999. La moyenne obtenue sur cette section a retourné 20,2 g/t Au sur 4,30 mètres (0.59 oz/t Au sur 13.97 pieds). Cette zone devrait être décapée sur toutes ses extensions (est et ouest) pour être complètement évaluée.

Un échantillonnage en vrac de 45 kilos fût prélevé sur des dykes de lamprophyres mafiques localement bréchifiés situés à proximité de l'indice Massé. Trois échantillons d'environ 16 kilos furent acheminés aux laboratoires en Saskatchewan (Saskatchewan Research Council) pour compléter une analyse par dissolution caustique afin d'y déterminer la présence de diamants.

SONDAGES AU DIAMANT (CAMPAGNE ÉTÉ-AUTOMNE 2000)

La campagne de sondages au diamant s'est déroulées du 08 au 23 août 2000. Un total de 1 258 mètres (4 127 pieds) répartis sur 10 sondages (1404-08 à 1404-17) a été

foré sur les zones aurifères Pierre Extension, Giaro et Shear Ekomiak localisées spécifiquement le long de la bordure est et sud de la propriété Yasinski-nord. Le contrat de forage fut octroyé à la firme Garant et Frères Limitée, de d'Alembert (Québec). Le tableau 3 résume les paramètres techniques de ces sondages au diamant.

Tableau 3 : Paramètres techniques des forages au diamant

| CIBLE | NO. SONDRAGE | COORDONNÉES | | AZIMUTH (Degrés) | PENDAGE (Degrés) | LONGUEUR Mètres (pieds) |
|---------------------|--------------|-------------|---------|---------------------|---------------------|----------------------------|
| | | LIGNE | STATION | | | |
| I.P. DEEP PIERRE | 1404-08 | 11+01W | 7+73S | 360 | -60 | 371.5 (1 219) |
| SHEAR EKOMIAK | 1404-09 | 10+50W | 6+00S | 200 | -45 | 48 (157) |
| PIERRE | 1404-10 | 11+29W | 5+50S | 200 | -45 | 123 (403) |
| PIERRE | 1404-11 | 11+79W | 5+71S | 187 | -45 | 138 (453) |
| PIERRE | 1404-12 | 12+30W | 5+40S | 180 | -45 | 108 (354) |
| GIARO | 1404-13 | 8+73W | 4+58S | 355 | -46.5 | 40.5 (133) |
| GIARO | 1404-14 | 8+64W | 4+26S | 183 | -45 | 75 (246) |
| PIERRE | 1404-15 | 10+66W | 5+76S | 202 | -50 | 120 (394) |
| PIERRE | 1404-16 | 11+13W | 5+72S | 195 | -45 | 120 (394) |

INDICE PIERRE

Sondage 1404-08 (Mort terrain : 2,0 mètres)

Ce sondage avait pour but la vérification d'une anomalie I.P. profonde sous l'indice de surface. Des sédiments gris verdâtres, aphanitiques, localement littés, rubanés et foliés furent recoupés de 2,00 à 270,13 mètres; suivi par des unités volcanosédimentaires et des basaltes entre 270,13 et 371,50 mètres. De 79,97 à 86,87

mètres, le sondage a recoupé le conglomérat Ekomiak de couleur gris à vert foncé, avec une matrice de silstone et des fragments subarrondis à arrondis de différentes natures et origines. Entre 118,20 et 221,00 une alternance de basalte et de sédiments fins furent recoupés avec plusieurs zones de veinules de quartz-carbonate, et traces de pyrite. Aucune minéralisation aurifère significative ne fut reconnue par ce sondage. Le nombre total d'échantillons est de 163 pour 67,26 mètres échantillonnés et le sondage fut arrêté à 371,50 mètres.

Sondage 1404-10 (Mort terrain : 3,0 mètres)

Ce sondage avait pour but la vérification de l'extension vers l'est de cet indice de surface où une anomalie PP de basse résistivité et de chargeabilité moyenne fût interprétée par Quantec. Des volcanosédiments gris verdâtres, aphanitiques, localement littés, rubanés et foliés et des basaltes, ainsi que quelques dykes de monzonites furent recoupés de 3,00 à 29,08 mètres. De 29,08 à 104,67 mètres, le sondage a recoupé une monzonite à porphyres de quartz-feldspath de couleur gris rosé, à grain grenu localement très cisailé et folié. Une intense altération en silice et carbonate montrant l'altération hydrothermale est observée. De nombreuses veines et veinules de quartz-ankérite contenant de 1 à 5% de pyrite se présentent parallèle à subparallèle à la foliation ainsi que de façon réticulaire à certains endroits. La zone minéralisée est localement bréchifiée, mylonitisée, séricitisée et marquée par de nombreuses injections de veines et veinules de quartz-carbonate. Localement, le contenu en pyrite peut atteindre jusqu'à 5% sous forme disséminée à semi-massive. Entre 42,67 et 44,93 mètres, une moyenne de **1,81 g/t Au (0.06 oz/t Au) et 1,4 g/t Ag (0.041 oz/t Ag) sur 2,26 mètres (7.41 pieds)** fut obtenue. Le nombre total d'échantillons est de 283 pour un total de 118,70 mètres échantillonnés et le sondage fut arrêté à 123 mètres.

Sondage 1404-11 (Mort terrain : 4,0 mètres)

Ce sondage avait pour but la vérification de l'extension vers l'ouest de cet indice de surface coïncident avec une petite anomalie de basse résistivité et de chargeabilité

moyenne. Des volcanosédiments gris verdâtres, aphanitiques, localement littés, rubanés et foliés avec une zone bréchique bordent la monzonite entre 4,00 – 11,21 mètres et 80,25 – 138,00 mètres. La monzonite qui occupe entre 11,21 et 80,25 mètres, est caractérisée par une intrusion à porphyres de quartz-feldspath de couleur gris rosé, à grain grenu localement très cisailé et folié. Localement, une altération en silice et carbonate montrant l'altération hydrothermale est observée. De nombreuses veines et veinules de quartz-ankérite contenant de 1 à 5% de pyrite se présentent parallèle à subparallèle à la foliation ainsi que de façon réticulaire à certains endroits, principalement dans des zones bréchiques. Les secteurs minéralisés sont caractérisés par des zones bréchifiées, mylonitisées, séricitisées et marquées par de nombreuses injections de veines et veinules de quartz-carbonate. Localement, le contenu en pyrite peut atteindre jusqu'à 5% sous forme disséminée à semi-massive. De 82,36 à 138,00 mètres la roche est principalement un silstone avec localement des zones fortement hématisées contenant plus de 25% de pyrite disséminée. Entre 17,64 et 18,10 mètres, une moyenne de **2,35 g/t Au (0.07 oz/t Au) et 0,5 g/t Ag (0.015 oz/t Ag) sur 0,46 mètre (1.51 pieds)** fut obtenue. Le nombre total d'échantillons est de 273 pour un total de 134 mètres échantillonnés et le sondage fut arrêté à 138 mètres.

Sondage 1404-12 (Mort terrain : 1,5 mètres)

Ce sondage avait pour but la vérification de l'extension vers l'ouest de l'indice Pierre de surface. Des volcanosédiments gris verdâtres, aphanitiques, localement littés, rubanés et foliés avec des séquences de basaltes qui bordent la monzonite entre 4,00 – 7,24 mètres et 95,72 – 108,00 mètres furent recoupés. La monzonite qui occupe entre 7,24 et 95,72 mètres, est caractérisée par une intrusion à porphyres de quartz-feldspath de couleur gris rosé, à grain grenu localement très cisailée et foliée. Localement, une altération en silice et carbonate montrant l'altération hydrothermale est observée. De nombreuses veines et veinules de quartz-ankérite contenant de 1 à 5% de pyrite se présentent parallèle à subparallèle à la foliation ainsi que de façon réticulaire à certains endroits, principalement dans des zones bréchiques. Les secteurs minéralisés sont caractérisés par des zones bréchifiées, mylonitisées, séricitisées et marquées par de

nombreuses injections de veines et veinules de quartz-carbonate. Localement, le contenu en pyrite peut atteindre jusqu'à 2% sous forme disséminée à semi-massive. De 82,36 à 138,00 mètres la roche est principalement un silstone avec localement des zones fortement hématisées contenant plus de 25% de pyrite disséminée. Entre 46,55 et 53,28 mètres la moyenne des teneurs obtenues fut de **1,54 g/t Au (0.05 oz/t Au) et 0,6 g/t Ag (0.017 oz/t Ag) sur 6,73 mètres (22.08 pieds)**. Le nombre total d'échantillons est de 227 pour un total de 106,01 mètres échantillonnés et le sondage fut arrêté à 108 mètres.

Sondage 1404-15 (Mort terrain : 4,0 mètres)

Ce sondage avait pour but la vérification de l'extension vers le sud de l'indice Pierre de surface à la limite est de l'anomalie PP de basse résistivité. Des sédiments gris verdâtres, aphanitiques, localement littés, rubanés et foliés furent recoupés entre 4,00 – 78,31 mètres. Plusieurs zones de veinules de quartz-carbonate furent recoupées. Un conglomérat du type Ekomiak fut aussi recoupé. De 78,31 à 101,00 mètres le sondage a recoupé des alternances de basaltes et de tufs mafiques avec un dyke de monzonite porphyrique entre 88,13 et 95,00 mètres. De 101,00 à 120,00 mètres la roche est dominée par un silstone avec quelques minces zones de brèches. De nombreuses veines et veinules de quartz-ankérite contenant de 1 à 3% de pyrite se présentent parallèle à subparallèle à la foliation ainsi que de façon réticulaire à certains endroits, principalement dans la séquence sédimentaires du début du sondage. Entre 44,10 et 45,60 mètres, une moyenne de **1,33 g/t Au (0.04 oz/t Au) et 2,4 g/t Ag (0.07 oz/t Ag) sur 1,50 mètres (4.92 pieds)** fût obtenue. Le nombre total d'échantillons est de 197 pour un total de 111,64 mètres échantillonnés et le sondage fût arrêté à 120 mètres.

Sondage 1404-16 (Mort terrain : 4,0 mètres)

Ce sondage avait lui aussi pour but de vérifier l'extension vers le sud de l'indice Pierre. Des sédiments gris verdâtres, aphanitiques, localement littés, rubanés et foliés furent recoupés entre 4,00 – 23,44 mètres. Plusieurs zones de veinules de quartz-carbonate furent recoupées. Un conglomérat du type Ekomiak fut aussi recoupé. De

23,44 à 82,08 mètres le sondage a recoupé la monzonite porphyrique. Les secteurs minéralisés sont caractérisés par des zones bréchifiées, mylonitisées, séricitisées et marquées par de nombreuses injections de veines et veinules de quartz-carbonate. Localement, le contenu en pyrite peut atteindre jusqu'à 2% sous forme disséminée à semi-massive. De 82,08 à 120,00 mètres des basaltes et des sédiments en alternances furent recoupés. Entre 50,36 et 52,70 mètres, une moyenne de **2,77 g/t Au (0.09 oz/t Au) et 4,7 g/t Ag (0.137 oz/t Ag) sur 2,34 mètres (7.68 pieds)** fut obtenue. Le nombre total d'échantillons est de 254 pour un total de 109,74 mètres échantillonnés et le sondage fut arrêté à 120 mètres.

Sondage 1404-17 (Mort terrain : 4,0 mètres)

Ce sondage avait pour but la vérification de l'extension en profondeur de l'indice Pierre sous le sondage 1404-03. Des volcanosédiments gris verdâtres, aphanitiques, localement littés, rubanés et foliés furent recoupés de 4,00 à 30,69 mètres. De 30,69 à 97,65 mètres, le sondage a recoupé une monzonite à porphyres de quartz-feldspath de couleur gris rosé, à grain grenu localement très cisailé et folié. Une intense altération en silice et carbonate montrant l'altération hydrothermale est observée. De nombreuses veines et veinules de quartz-ankérite contenant de 1 à 5% de pyrite se présentent parallèle à subparallèle à la foliation ainsi que de façon réticulaire à certains endroits. La zone minéralisée est localement bréchifiée, mylonitisée, séricitisée et marquée par de nombreuses injections de veines et veinules de quartz-carbonate. Localement, le contenu en pyrite peut atteindre jusqu'à 20% sous forme disséminée à semi-massive. De 97,65 à 114,00 mètres une alternance de basalte et de sédiments furent recoupés. La zone Pierre a révélé une intersection de **0,76 g/t Au (0.02 oz/t Au) et 2,4 g/t Ag (0.07 oz/t Ag) sur 34,28 mètres (112.47 pieds)**. Le nombre total d'échantillons est de 231, totalisant 104,53 mètres de carottes échantillonnées. Le sondage fut arrêté à 114,00 mètres.

SHEAR EKOMIAK

Sondage 1404-09 (Mort terrain : 2,4 mètres)

Ce sondage avait pour but la vérification du cisaillement Ékomiak qui coïncide avec une mince zone de haute résistivité orientée E-W. Des volcanosédiments gris verdâtres, aphanitiques, localement littés, rubanés et foliés avec une séquence de conglomérats (Ékomiak) furent recoupés sur la longueur du sondage. De 10,85 à 15,03 mètres, le sondage a recoupé des silstones et des grès fortement séricitisés et silicifiés avec de nombreuses veines et veinules de quartz-ankérite contenant de 2 à 15% de pyrite disséminées. Localement de petites zones de cisaillements furent recoupées et caractérisées par une bréchification, mylonitisation, séricitisation et marquée par de nombreuses injections de veines et veinules de quartz-carbonate. Entre 11,29 et 15,80 mètres, une moyenne de **1,06 g/t Au (0.03 oz/t Au) et 1,7 g/t Ag (0.05 oz/t Ag) sur 4,51 mètres (14.80 pieds)** fut obtenue. Le nombre total d'échantillons est de 87, totalisant 37,31 mètres de carottes échantillonnées. Le sondage fut arrêté à 48,00 mètres.

INDICE GIARO

Sondage 1404-13 (Mort terrain : 2,0 mètres)

Ce sondage avait pour but la vérification de l'extension en profondeur de cet indice de surface. Tout le sondage a recoupé une monzonite à porphyres de quartz-feldspath de couleur gris rosé, à grain grenu localement très cisailé et folié. Une intense altération en hématite, silice et carbonate montrant l'altération hydrothermale est observée. Quelques veines et veinules de quartz-ankérite contenant de 1 à 3% de pyrite se présentent parallèle à subparallèle à la foliation ainsi que de façon réticulaire à certains endroits. De 97,65 à 114,00 mètres une alternance de basalte et de sédiments furent recoupés. Entre 17,47 et 19,06 mètres, une moyenne de **1,82 g/t Au (0.06 oz/t Au) et 4,3 g/t Ag (0.126 oz/t Ag) sur 1,59 mètres (5.22 pieds)** fut obtenue. Le nombre total

d'échantillons est de 62, totalisant 38,50 mètres de carottes échantillonnées. Le sondage fut arrêté à 40,50 mètres.

Sondage 1404-14 (Mort terrain : 3,75 mètres)

Ce sondage avait pour but la vérification de l'extension en profondeur et à l'est de cet indice de surface. De 3,75 à 40,60 mètres, le sondage a recoupé une monzonite à porphyres de quartz-feldspath de couleur gris rosé, à grain grenu localement très cisailé et folié. Une intense altération en hématite, silice et carbonate montrant l'altération hydrothermale est observée. Quelques veines et veinules de quartz-ankérite contenant de 1 à 3% de pyrite se présentent parallèle à subparallèle à la foliation ainsi que de façon réticulaire à certains endroits. De 40,60 à 75,00 mètres une alternance de basalte et de sédiments furent recoupés, incluant un conglomérat polygénique avec quelques veinules de quartz-carbonate. Entre 22,62 et 24,98 mètres, une moyenne de **2,37 g/t Au (0.08 oz/t Au) et 4,30 g/t Ag (0.126 oz/t Ag) sur 2,36 mètres (7.74 pieds)** fut obtenue. Le nombre total d'échantillons est de 116, totalisant 56,25 mètres de carottes échantillonnées. Le sondage fut arrêté à 75,00 mètres.

RÉVISION DE LA MÉTHODE D'ANALYSE DES ÉCHANTILLONS DE CAROTTE DE FORAGE

Suite a des difficultés de représentativité d'échantillonnage concernant quelques résultats d'analyses aurifères plus petits que 2 g/t Au, une procédure efficace et plus économique de traitement des échantillons de carotte fût mise au point pour obtenir des résultats précis et continus de ces analyses.

La majeure partie des échantillons rééchantillonnés fût tirée des sondages 1404-03 et 1404-17. Au total, 54 échantillons furent sélectionnés pour réanalyse et les résultats apparaissent en annexe .

Cette étude fût réalisée par M. John Ryder. En voici les grandes lignes :

- 1- En général les résultats provenant de l'analyse par gravimétrie sont plus faibles que ceux obtenus par géochimie (Au+35).
- 2- Les résultats d'analyse de la carotte (Monzonite porphyrique) furent vérifiés si l'or grossier causait une distorsion des analyses.
- 3- Les études pétrographiques effectuées sur le porphyre minéralisé montrent que l'or se présente le plus souvent encapsulé dans la pyrite et mesure entre 3 et 9 microns. La présence de l'or associé entre 3 et 9 microns. La présence de l'or associé au quartz ainsi qu'à la pyrite requiert une meilleure compréhension de l'effet du broyage et de la pulvérisation sur la détermination de la distribution de l'or. Les échantillons furent broyés et moulus à -150, 200 et 250 mesh et pulvérisés à la dimension requise. L'analyse pour l'or fût faite par Absorption Atomique (AA-Au +30) en utilisant 30 grammes par échantillon.
- 4- Les résultats de ces tests démontrent clairement :
 - a) Des teneurs basses en or pour les pulvérisations à -250 mesh probablement dû à un épandage sur les disques de pulvérisation.
 - b) Les échantillons plus élevés que 3 g/t Au montrent des teneurs et variations acceptables.
 - c) Peu de variations entre -150 et -200 mesh ayant des teneurs plus élevées que 3 g/t Au.
 - d) Variations de teneurs aurifères non acceptable pour les résultats plus faibles que 3 g/t Au.
 - e) Des variations majeures des teneurs aurifères entre le broyage -150 et -200 mesh pour les résultats plus petits que 3 g/t Au.
- 5- Des variations de 12% à 42% des teneurs aurifères plus petits que 3 g/t Au sont inacceptables. Les causes possibles peuvent être :
 - a) Un manque d'homogénéité des procédures d'analyse incluant une technique de cartage inadéquate (distribution inégale des particules or/pyrite).
 - b) Le volume de l'échantillon trop petit (30 grammes) menant à une distribution inégale pyrite/or.
 - c) Le broyage par « ball mill » serait-il inadéquat pour ce type d'échantillon?

- d) La méthodologie d'analyse.
- 6- Une distribution inégale de l'or dans la pyrite peut créer des difficultés à reproduire des analyse fiables. Pour cette raison, neuf (9) échantillons furent sélectionnés et préparés selon cinq (5) étapes à suivre :
- a) Chaque échantillon broyé à $\frac{1}{4}$ de pouce puis rebroyé et tamisé à -10 mesh.
 - b) Tout l'échantillon broyé à -10 mesh est ensuite pulvérisé à -150 mesh et bien mélangé.
 - c) L'échantillon tamisé à -150 mesh est carté et séparé en deux. Une des deux demies est ensuite pulvérisée à -200 mesh. Les échantillons -150 et -200 mesh sont ensuite mélangés et homogénéisés avant d'être recartés.
 - d) Chaque échantillon (-150 et -200 mesh) sont ensuite séparés en échantillons de 50 grammes chacun pour chaque fraction de dimension de pulvérisation prévue (-150, -200 mesh, etc.).
 - e) Tous les échantillons de -150 et -200 mesh sont ensuite analysés pour l'or par pyroanalyse (Au50, FA50) au laboratoire de Chimitec Bondar-Clegg à Val-d'Or (Québec).
- 7- Suite aux résultats obtenus, nous constatons que les variations entre les différents échantillons sont à l'intérieur de limites acceptables :
- a) Il y a très peu de variation entre les échantillons tamisés à -150 et -200 mesh. La moyenne de différence entre les fractions tamisées est de 4%.
 - b) La fraction -150 mesh a donné de meilleures teneurs aurifères que la fraction -200 mesh.
 - c) Les fractions tamisées ont révélé une distribution de l'or relativement constante.
- 8- La préparation de l'échantillon (broyage, pulvérisation, cartage, etc.) selon de nouveaux critères a permis de surmonter les difficultés de variations de l'or.
- 9- Les étapes de préparation des échantillons et les méthodes d'analyse devraient être les suivantes :
- a) Broyer la carotte à $\frac{1}{4}$ de pouce.
 - b) Rebroyer à -10 mesh.
 - c) Mélanger et homogénéiser à -10 mesh.
 - d) Carter.

- e) Utiliser 250 grammes et remiser le reste de l'échantillon.
- f) Pulvériser le 250 grammes à -150 mesh.
- g) Mélanger et homogénéiser à -150 mesh.
- h) Prendre deux échantillons de 50 grammes.
- i) Remiser l'un d'entre eux pour référence et/ou duplicata.
- j) Passer l'autre 50 grammes à la pyroanalyse pour l'or.
- k) Analyser aussi pour l'argent.
- l) Ne plus analyser Au+35 par routine.
- m) Au+35 Geochem pour autres échantillons que la carotte de forage.
- n) Tous les échantillons de carottes révélant des teneurs plus élevées que 1 g/t Au devraient être vérifiés en analysant le duplicata.
- o) L'analyse par méthode gravimétrique ne doit être utilisée que sélectivement après avoir analysé le duplicata. Ensuite utiliser 2 Assay Ton pour l'autre échantillon.

AUTRES SUBSTANCES

Récemment, Aurora Platinum Corp. A annoncé la découverte d'une zone minéralisée en Ni-Cu-PGE recoupée par forages et associée à l'ancienne zone Midrim dans le Témiscamingue. Cet annonce a lancé l'activité et l'engouement pour les platinoïdes dans la région du Témiscamingue et aussi dans les autres secteurs dont le secteur de la Baie James. L'intersection la plus significative obtenue par Aurora dans leur sondage MR 00-01 a révélé : 19,7 mètres à 2.99% Cu, 1.85% Ni, 0.07% Co, 0,97 g/t Pt, 1,77 g/t PD et 0,48 g/t Au.

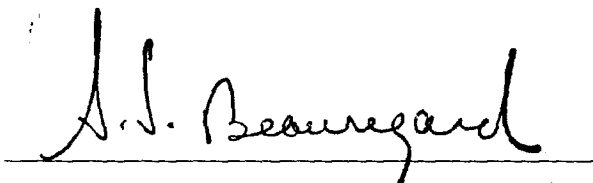

De plus, le secteur de la Baie James est aussi fébrile pour la prospection pour le diamant avec les récents travaux dans le secteur de Wéminji. La présence de dykes mafiques et ultramafiques sur les propriétés Yasinski-Nord et PEM 1404 pourraient présenter un potentiel pour la recherche de diamants et de platinoïdes.

CONCLUSIONS ET RECOMMANDATIONS

Les travaux récents ont permis de mieux définir les zones minéralisées aurifères antérieurement trouvées. Le levé TDIP-RESISTIVITY a détecté plusieurs réponses anormales modérées à fortes qui sont vraisemblablement associées à de la minéralisation disséminée dans la roche. Les forages au diamant et les décapages ont permis de constater que l'importante minéralisation aurifère se retrouve dans une intrusion du type latite (monzonite) porphyrique avec injection de quartz-carbonate et sulfures. A la lumière de ces résultats, il serait judicieux de poursuivre la prospection et la reconnaissance géologique des secteurs d'intérêt et sur l'ensemble des propriétés Yasinski-Nord et PEM 1404 afin de compléter la corrélation entre les signatures géophysiques relevées et la géologie et la minéralisation.

La poursuite des travaux devra comprendre de la prospection, de la cartographie géologique, des tranchées avec échantillonnage et un levé de till de base sur l'ensemble des propriétés Yasinski-Nord et PEM 1404, du décapage complémentaire avec du rainurage sur les secteurs Giaro et Benoît extension, un levé aéroporté (Mag et EM) sur l'ensemble des deux propriétés afin de mieux caractériser les zones minéralisées déjà connues et de reconnaître de nouvelles cibles géophysiques et indices de surface.

Respectueusement,

Alain-Jean Beauregard, géol., APGGQ, FGAC

Daniel Gaudreault, ing. Géol., APGGQ, APEGN

GM 10200 M.J. BOYLEN ENGINEERING - GEOLOGIST REPORT -PROJECT NO. 286- YASINSKI LAKE AREA. BALDWIN, H.B. (23 NOVEMBER, 1959)

Rapport de qualification complet sur les activités d'exploration et les travaux effectués en 1958 et 1959 dans la région du lac Yasinski. Le rapport inclut des cartes géologiques régionales et détaillées avec les anomalies géophysiques aéroportées ainsi que le suivi au sol avec la géophysique et la géologie détaillée. Il inclut de plus des tableaux récapitulant les faits saillants des cibles d'exploration et les résultats d'analyses géochimiques ainsi que des journaux de sondage des trous de forage au diamant effectués.

GM 33516 ÉTUDE D'ANOMALIE RADIOMÉTRIQUE DANS LE SECTEUR DU LAC MIAKADOW

Analyse et étude des anomalies radiométriques obtenues des corps intrusifs pegmatitiques felsiques se localisant dans l'encaissant gneissique dans la région de la sous-ceinture de roches vertes du lac Miakadow

GM 50180 PROPRIÉTÉ RADISSON (1241) - RAPPORT DES TRAVAUX EFFECTUÉS SUR LA PROPRIÉTÉ RADISSON DURANT L'ANNÉE 1989. CHAINEY ET AL. (17 AVRIL 1991)

Sommaire et rapport de qualification pour trois gros blocs, l'un d'entre eux incluant la région du lac Miakadow. Descriptions intralithologiques détaillées et analyse structurale. Le rapport fait suite à une évaluation lithogéochimique systématique des unités locales dans le but de déterminer la distribution des valeurs aurifères.

ANNEXE II – DRILL CORE – ANALYTICAL RESULTS (J. RYDER, 2001)

DATA SOURCES:

Discussions with the project geologist Mr. Marc Banas, consultant Mr. Alain Beauregard of Geologica and Dianor's field crew/prospectors was very informative and greatly assisted the author in his review. In addition, it became apparent that the large amount of field work completed on the PEM 1404 property since February 2000 and data derived therefrom will require careful study and evaluation upon receipt of the outstanding drill core analyses. Information and access to all documents, core logs, samples, maps, compilations, internal company and government reports etc. was freely given and all queries concerning the Project were answered promptly.

A list of reports, documents and professional publications utilized and reviewed for this report are attached as Appendix 1.

Site visits were made to the PEM 1404 property in the company of the project geologist and prospectors. Helicopter visits were made to specific areas in the vicinity of the PEM 1404 at the end of September.

Core from the summer (2000) drill program was inspected at the Camp.

Analytical data was processed by the author and results reviewed by both Mr. Banas and Mr. Beauregard.

DRILL CORE - ANALYTICAL RESULTS:

SUMMARY:

1. A good correlation was found between the geochemical results using Bondar Clegg's gold plus thirty five elements assay package (Au +35) and the Gravimetric finish assays used to check geochemical results that reported gold values greater than 2 g/t. In general, the Gravimetric gold results were slightly lower than the geochemical values.

2. Drill core samples representing the mineralized Porphyry Intrusion were selected to test whether free coarse gold was causing analytical distortion. Results of the testing clearly show that overall, the coarse free gold does not skew the results.

3. Petrographic work on core samples of gold bearing Porphyry showed that gold blebs from 3 microns to 9 microns enclosed in pyrite appeared to be one of the forms in which gold mineralization occurred. The presence of free gold associated with quartz plus "pyritic" gold (enclosed, microscopic) required that the gold variation within sample be understood and that the effect of grind size on the gold distribution be determined. A number of gold bearing Porphyry core samples were selected. The samples were ground/pulverized to minus 150, minus 200 and minus 250 mesh screen size. Crushing was by jaw crusher to 1/4 inch then ball milling to #10 mesh, followed by pulverizing to the required final mesh sizes. Analyses for gold was by AA (Au 30) using 30 grams per assay samples.

Results revealed that:

(a) Consistent low gold values were recorded for the minus 250 mesh screen size, regardless of gold grade. Possibly caused by smearing of gold on pulverizing disc.

(b) Acceptable gold value variations within samples were recorded from those samples assaying above 3g/t gold.

(c) There was little grade variation between the minus 150 and minus 200 mesh screen size samples having gold values above 3 g/t gold.

(d) There was an unacceptable gold value variations within samples assaying below 3 g/t gold.

(e) There was major gold grade variation between the minus 150 and minus 200 mesh fraction for those samples having gold values below 3 g/t gold.

4. The internal gold grade variations of 12% to 42%, within those samples reporting gold grades below 3 g/t, is **unacceptable**. The possible causes for this range of gold variation in these low grade gold samples are listed below:

(1) Lack of homogenization of samples throughout the laboratory sample processing procedures including sample splitting techniques. This leads to the uneven distribution of auriferous pyrite and free gold particles.

(2) Assay sample size. (30 grams -too small, leading to uneven auriferous pyrite free gold distribution)

(3) Ball milling of sample (not effective for this type of mineralized rock.)

(4) Assay methodology.

4. The uneven distribution of the gold in the Porphyry is a result of the different types/styles of gold mineralization (free/pyritic) occurring in the samples. Because of their low gold content (grade of <3g/t), a single grain of free gold and/or uneven distribution of auriferous pyrite grains can and will create problems with obtaining consistent, reproducible gold assays.

Based on this thesis a number of core samples were selected for re-analysis and sample preparations were modified to take the above ***(1 to 4)*** factors into account. Nine core samples of low grade Porphyry (< 3 g/t Au) were selected and the

following laboratory procedures were forwarded to Bondar Clegg for implementation:

- a. *Each sample was crushed to 1/4 inch size using a jaw crusher.*
- b. *All of the minus 1/4 inch sample was roll crushed to minus 10 mesh screen size.*
- c. *The minus 10 mesh sample was further crushed by pulverizing to minus 150 mesh, and blended thoroughly.*
- d. *The minus 150 mesh sample was split into two samples. One half was further pulverized to minus 200 mesh. Both the minus 150 and the minus 200 samples were further blended and homogenized prior to splitting.*
- e. *Each of the samples (-150, -200 mesh) were then split into a series of 50 gram "assay" samples for each size fraction until all of the pulverized sample was used up.*
- f. *All the minus 150 and minus 2000 mesh samples were then analyzed for gold by fire assay (Au 50, FA 50) at Bondar Clegg's laboratory.*

5. Results from five (5) of the nine (9) samples, (total sub-samples assayed was sixty two (62)) were received at the end of October and plotted. Results for the outstanding four (4) samples (total sub-samples sixteen (16)) were only received within the past few days.

It is apparent from these results that the gold value variations within the samples and between the samples are within acceptable limits and appear constant for each size fraction.

Results show:

(a) Very little variation in gold grade between the minus 150 and minus 200 size fractions. The average difference between the size fractions is in the order of 4%.

(b) The minus 150 mesh sized samples returned higher gold values than the minus 200 mesh samples when compared to the original analyses:

(c) The internal gold distribution within each sample for each of the two size fractions is relatively constant for each size fraction.

The minus 150 size fraction has a higher internal percentage gold difference (variation) at an average of 12% when compared to a 7% internal gold variation for the minus 200 size fraction .

6. It would appear from the preliminary results at hand that the sample preparation criteria and "assay" sample size utilized on the last batch of samples has overcome the "unacceptable" assays reported for the low grade gold (< 3g/t).

7. It is recommended that the following sample preparation criteria and assay methodology be implemented on the outstanding drill core (and channel samples) awaiting processing and analysis. :

SAMPLE PROCESSING/ASSAYING FOR DRILL CORE:

- #1. CORE CRUSHED TO 1/4 INCH.
- #2. FURTHER CRUSH TO MINUS 10 MESH USING ROLL CRUSHER
- #3. MIX/BLEND/HOMOGENIZE THE MINUS 10 MESH MATERIAL
- #4. SPLIT SAMPLE
- #5. FROM ONE SPLIT TAKE A 250 gram SAMPLE. STORE REST OF SAMPLE.

- #6. PULVERIZE THE 250 GRAM SAMPLE TO MINUS 150 .
- #7. MIX/BLEND/HOMOGENIZE THE MINUS 150 PULVERIZED MATERIAL
- #8. TAKE TWO 50 gram SAMPLES.
- #9. STORE ONE SAMPLE FOR REFERENCE AND POSSIBLE DUPLICATE ASSAY.

- #10. FIRE ASSAY THE OTHER 50 gram SAMPLE (FA 50 CODE) FOR GOLD.
- #11. SILVER THE ONLY OTHER ELEMENT TO BE ASSAYED FOR.
- #12. NO LONGER ANALYSES FOR OTHER ELEMENTS ROUTINELY.
- #13. THE Au +35 GEOCHEMICAL MULTI - ELEMENT PACKAGE TO BE ONLY USED FOR NON-DRILL CORE MATERIAL UNLESS SPECIFIED.
- #14. ALL CORE SAMPLES RETURNING GOLD VALUES GREATER THAN ONE GRAM A TONNE (1 g/t) SHOULD BE ROUTINELY CHECKED BY ANALYZING THE DUPLICATE SAMPLE REFERENCE #9 ABOVE.
- #15. GRAVIMETRIC FINISH ONLY TO BE USED SELECTIVELY AFTER DUPLICATE RESULTS ARE AVAILABLE. THEN USE TWO (2) ASSAY TON SAMPLES FOR GRAVIMETRIC ANALYSES.

GEOLOGICA
JOURNAL DE SONDAGE

Propriété: 1404

Trou no: 1404-10
Canton :
Lot :

Zone no:

Contracteur: Garant & Frères

Débuté le: 14/08/1900
Terminé le: 15/08/1900

Rang :

Claim no: PEM 1404

Niveau :

Section:

Lieu de travail:

Coordonnées au collet :

Ligne : 11+29 w
Station: 5+50 s

Latitude: 5919423.56N
Longitude: 337974.73E
Élévation: 173.50 M

Azimut: 200° 0' 0"
Inclinaison: -45° 0' 0"
Longueur: 123.00 M

Système de référence:

Arpenté par:

Tests de déviation :

| Profondeur | Inclinaison | Az Corrigé |
|------------|-------------|------------|
| 90.00 M | -47° 0' 0" | ° ' " |
| 120.00 M | -46° 0' 0" | ° ' " |

Remarques : Pierre showing - east extension

Débit d'eau:
Cimenté :

Bouchon:
Dimension de la carotte: NQ

Journal par: M. Banas, geologist

Rédigé le: 16/08/1900

Trou no: 1404-10
